

# 1 Homology

## 1.1 Basic definitions and examples

### 1.1.1 Ordinary homology

Singular homology is the study of topological spaces by associating to them chain complexes in the following way.

$$\mathbf{Top} \xrightarrow{\text{singular nerve}} \mathbf{Set}_\Delta \xrightarrow{\text{free abelian group}} \mathbf{Ab}_\Delta \xrightarrow{\text{Dold-Kan correspondence}} \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$$

**Definition 1** (singular complex, singular homology). Let  $X$  be a topological space. The singular chain complex  $S_\bullet(X)$  is defined level-wise by

$$S_n(X) = M(\mathcal{F}(\mathbf{Sing}(X)))$$

where  $\mathcal{F}$  denotes the free group functor and  $M$  is the Moore functor (Definition ??). That is, it has differentials

$$d_n: S_n \rightarrow S_{n-1}; \quad (\alpha: \Delta^n \rightarrow X) \mapsto \sum_{i=0}^n \partial^i \alpha.$$

The singular homology of  $X$  is the homology

$$H_n(X) = H_n(S_\bullet(X)).$$

Note that the singular chain complex construction is functorial: any map  $f: X \rightarrow Y$  gives a chain map  $S(f): S(X) \rightarrow S(Y)$ . This immediately implies that the  $n$ th homology of a space  $X$  is invariant under homeomorphism.

**Example 2.** Denote by  $\text{pt}$  the one-point topological space. Then  $\mathbf{Sing}(\text{pt})_n = \{*\}$ , and the chain complex  $S_\bullet(\text{pt})$  is at each level simply  $\mathbb{Z}$ .

The differential  $d_n$  is given by

$$d_n = \sum_{i=0}^n (-1)^i \partial^i; \quad * \mapsto \sum_{i=0}^n (-1)^i *.$$

## 1 Homology

If  $n$  is odd, then there are as many summands with even sign as there are with odd sign, and they cancel each other out. If  $n$  is even, then there is one more term with positive sign than with negative sign, and one ends up with the identity. Thus  $S(\text{pt})_\bullet$  is given level-wise as follows.

$$\begin{array}{ccccccccccccccc} \cdots & \xrightarrow{\text{id}} & \mathbb{Z} & \xrightarrow{0} & \mathbb{Z} & \xrightarrow{\text{id}} & \mathbb{Z} & \xrightarrow{0} & \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \cdots \\ & & \parallel & & \parallel & & \parallel & & \parallel & & \parallel & & \\ \cdots & \xrightarrow{d_4} & S_3 & \xrightarrow{d_3} & S_2 & \xrightarrow{d_2} & S_1 & \xrightarrow{d_1} & S_0 & \xrightarrow{d_0} & S_{-1} & \xrightarrow{d_{-1}} & \cdots \end{array}$$

Thus, the  $n$ th homology of the point is

$$H_n(\text{pt}) = \begin{cases} \mathbb{Z}, & n = 0 \\ 0, & n \neq 0 \end{cases}.$$

### 1.1.2 Reduced homology

Recall that in addition to the *ordinary*, or *topologist's simplex category*  $\Delta$ , there is the so-called *extended*, or *algebraist's simplex category*  $\Delta_+$ , which includes the object  $[-1] = \emptyset$ . If we use this category to index our simplicial sets, our chain complexes have a term  $\tilde{S}_{-1} = \mathbb{Z}$ . It is traditional to denote the differential  $d_0: \tilde{S}_0 \rightarrow \tilde{S}_{-1}$  by  $\varepsilon$ , and call it the *augmentation map*.

$$\cdots \longrightarrow \tilde{S}_2 \xrightarrow{d_2} \tilde{S}_1 \xrightarrow{d_1} \tilde{S}_0 \xrightarrow{\varepsilon} \mathbb{Z} \longrightarrow 0$$

**Definition 3** (reduced singular chain complex). The chain complex  $\tilde{S}$  is called the reduced singular chain complex of  $X$ .

We see immediately that

$$S_i(X) = \tilde{S}_i(X), \quad i \geq 0,$$

implying

$$H_i(X) = \tilde{H}_i(X), \quad i \geq 1.$$

The difference between ordinary and reduced homology is that, as one might suspect, ordinary homology is better-behaved from a topological point of view, and reduced homology is better behaved algebraically (for example, as a functor reduced homology turns wedge products into direct sums).

There is also another interpretation of reduced homology. Recall that we have used the name *augmentation map* before, when dealing with resolutions. There we reinterpreted the augmentation map  $\varepsilon$  as a chain map to a complex concentrated in degree zero. We can pull exactly the same trick here, viewing the augmentation map as a map of chain

complexes

$$\begin{array}{ccccccc} \cdots & \longrightarrow & S_2 & \xrightarrow{d_2} & S_1 & \xrightarrow{d_1} & S_0 \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \varepsilon \\ \cdots & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} \longrightarrow 0 \end{array}.$$

**Example 4.** We can immediately read off that the reduced homology of the point is

$$\tilde{H}_n(\text{pt}) = 0 \quad \text{for all } n.$$

**Example 5.** Let  $X$  be a nonempty path-connected topological space. Then  $H_0(X) \cong \mathbb{Z}$ . Specifically,

$$\varepsilon: H_0(X) \rightarrow \mathbb{Z}$$

is an isomorphism.

To see this, let  $x \in S_0(X)$  be a point. Since  $\varepsilon(nx) = n$  for any  $n \in \mathbb{Z}$ , we know that  $\varepsilon$  is surjective. If we can show that  $\varepsilon$  is injective, then we are done.

At face value,  $\varepsilon$  does not look injective; after all, there are as many elements of  $S_0(X)$

consider a general element of  $H_0(X)$ . Because  $d_0$  is the zero map,  $H_n(X)$  is simply the free group generated by the collection of points of  $X$  modulo the relation “there is a path from  $x$  to  $y$ .” However, path-connectedness implies that every two points of  $X$  are connected by a path, so every point of  $X$  is equivalent to any other. Thus,  $H_0(X)$  has only one generator.

**Example 6.** More generally, for any (not necessarily path connected) space  $X$ ,

$$H_0(X) = \mathbb{Z}^{\pi_0(X)}.$$

Suppose that  $X$  can be written as a disjoint union

$$X = \bigsqcup_i X_i.$$

Then, since a map

$$\sigma: \Delta^n \rightarrow X$$

cannot hit more than one of the  $X_i$ , we have

$$\mathbf{Top}\left(\Delta^n, \bigsqcup_i X_i\right) \cong \bigsqcup_i \mathbf{Top}(\Delta^n, X_i).$$

Thus, since the free abelian group functor  $\mathcal{F}$  and the Moore functor  $M$  are both left adjoints, they preserve colimits and we have

$$S_n\left(\bigsqcup_i X_i\right) \cong \bigoplus_i S_n(X_i).$$

We will come back to reduced homology in [Section 1.7](#), when we have the tools to understand it properly.

## 1.2 The Hurewicz homomorphism

Let  $X$  be a topological space, and let  $x \in X$ . Let  $\gamma$  be a loop in  $X$  which starts and ends at  $x$ , i.e.

$$\gamma: \Delta^1 \rightarrow X; \quad \gamma(0) = x = \gamma(1).$$

We can view  $\gamma$  either as a singular 1-simplex in  $X$ , or as a representative of a homotopy class in  $\pi_1(X, x)$ . It turns out that these points of view are compatible.

**Lemma 7.** The assignment  $\gamma \mapsto [\gamma]_{H_1}$  respects homotopy, and thus descends to a map of sets out of  $\pi_1(X, x)$ .

$$\begin{array}{ccc} \left\{ \begin{array}{l} \text{Loops starting and} \\ \text{ending at } x \end{array} \right\} & \xrightarrow{\text{homology class}} & H_1(X) \\ \text{homotopy class} \downarrow & \searrow \exists! \tilde{h}_X & \\ \pi_1(X, x) & & \end{array}$$

*Proof.* Let  $\gamma_1$  and  $\gamma_2$  be loops based at  $x$ .

First, suppose that  $\gamma_1 \stackrel{H}{\sim} \gamma_2$ , i.e.

In order to see that □

The map  $\tilde{h}_X$  is very well-behaved.

**Lemma 8.** For a topological space  $X$  and point  $x \in X$ , the map

$$\tilde{h}_X: \pi_1(X, x) \rightarrow H_1(X)$$

is a group homomorphism.

*Proof.* We need to show that it sends the identity to the identity and respects composition. □

Because  $H_1(X)$  is abelian,  $\tilde{h}_X$  descends to a map out of  $\pi_1(X, x)_{\text{ab}}$ .

**Definition 9** (Hurewicz homomorphism). Let  $X$  be a path-connected topological space, and let  $x \in X$ . The Hurewicz homomorphism is the map

$$h_X: \pi_1(X, x)_{\text{ab}} \rightarrow H_1(X).$$

**Theorem 10** (Hurewicz). For any path-connected topological space  $X$ , the Hurewicz homomorphism is an isomorphism

$$h_X: \pi_1(X, x_0)_{\text{ab}} \cong H_1(X),$$

where  $(-)_{\text{ab}}$  denotes the abelianization. Furthermore, the maps  $h_X$  form the components of a natural isomorphism.

$$\begin{array}{ccc} & \xrightarrow{(\pi_1)_{\text{ab}}} & \\ \text{Top}_* & \Downarrow h & \text{Ab} \\ & \xleftarrow{H_1} & \end{array}$$

*Proof.* We construct an inverse explicitly.

For each point  $x \in X$ , pick a path

$$\gamma_x: \Delta^1 \rightarrow X; \quad \gamma_x(0) = x_0, \quad \gamma_x(1) = x$$

connecting  $x_0$  to  $x$ . For  $x = x_0$ , choose  $\gamma_{x_0}$  to be the constant path.

For each generator  $\alpha: \Delta^1 \rightarrow X$  in  $H_1(X)$ , the concatenation

$$\gamma_{\alpha(0)} * \alpha * \overline{\gamma_{\alpha(1)}}$$

is a path starting and ending at  $x$ . We may thus define a map

$$\phi: S_1(X) \rightarrow \pi_1(X, x)_{\text{ab}}$$

on generators by

$$\alpha \mapsto [\gamma_{\alpha(0)} * \alpha * \overline{\gamma_{\alpha(1)}}],$$

and addition via

$$\alpha + \beta \mapsto [\gamma_{\alpha(0)} * \alpha * \overline{\gamma_{\alpha(1)}}][\gamma_{\beta(0)} * \beta * \overline{\gamma_{\beta(1)}}].$$

In order to check that defining this homomorphism on generators descends to a map on homology, we have to check that it sends boundaries  $\partial\sigma$  to zero.  $\square$

**Example 11.** We can now confidently say that

$$H_1(\mathbb{S}^1) = \pi_1(\mathbb{S}^1)_{\text{ab}} = \mathbb{Z},$$

and that

$$H_1(\mathbb{S}^n) = 0, \quad n > 1.$$

**Example 12.** Denote by  $\Sigma_g$  the two-dimensional surface of genus  $g$ . We know that

$$\pi_1(\Sigma_g) = \langle a_1, b_1, \dots, a_{2g}, b_{2g} \mid \prod_{i=1}^g [a_i, b_i] \rangle.$$

The abelianization of this is simply  $\mathbb{Z}^{2g}$ , so

$$H_1(\Sigma_g) = \mathbb{Z}^{2g}.$$

**Example 13.** Since

$$\pi_1(X \times Y) \equiv \pi_1(X) \times \pi_1(Y)$$

and

$$\pi_1(X \vee Y) \equiv \pi_1(X) * \pi_1(Y),$$

we have that

$$H_1(X \times Y) \cong H_1(X) \times H_1(Y) \cong H_1(X \vee Y).$$

### 1.3 The method of acyclic models

We need to break the flow here for a theorem which will show up several times, called the *method of acyclic models*.

**Definition 14** (category with models). A category with models is a pair  $(\mathcal{C}, \mathcal{M})$ , where  $\mathcal{C}$  is a category and  $\mathcal{M} \subset \text{Obj}(\mathcal{C})$  is a set of objects of  $\mathcal{C}$ .

**Definition 15** (free, acyclic functor). Let  $(\mathcal{C}, \mathcal{M})$  be a category with models, and let  $F: \mathcal{C} \rightarrow \mathbf{Ch}_{\geq 0}(R\text{-}\mathbf{Mod})$ .

1. We say that  $F$  is acyclic on  $\mathcal{M}$  if for each  $M \in \mathcal{M}$ ,  $F(M)$  is acyclic in positive degree, i.e. if  $H_n(F(M)) = 0$  for  $n > 0$ .
2. Let  $J$  be a set, and  $\mathcal{M}_J \subset \mathcal{M}$  a  $J$ -indexed set of objects in  $\mathcal{M}$ . Note that we allow the possibility that each  $M \in \mathcal{M}$  can appear more than once in  $\mathcal{M}_J$ , or not at all.

Let  $F_*: \mathcal{C} \rightarrow R\text{-}\mathbf{Mod}$  be a functor. An  $\mathcal{M}_J$ -basis for  $F_*$  is, for each  $j \in J$  an element  $m_j \in F_*(M_j)$  (forming an indexed collection  $\{m_j \in F_*(M_j)\}_{j \in J}$ ) such that for any  $X \in \mathcal{C}$  the indexed collection

$$\{F_*(f)(m_j)\}_{j \in J, f \in \text{Hom}(M_j, X)}$$

is a basis for  $F_*(X)$  as a free  $R$ -module; that is, that we can write

$$F_*(X) = \mathbb{Z}\{F_*(f)(m_j)\}_{j \in J, f \in \text{Hom}(M_j, X)}.$$

We say that  $F$  is free on  $\mathcal{M}$  if for each  $q \geq 0$  there exists some set  $J_q$  and indexed set  $\mathcal{M}_{J_q}$  such that each  $F_q$  has an  $\mathcal{M}_{J_q}$ -basis.

**Example 16.** Consider the category  $\mathbf{Top}$  with models  $\{\Delta^n\}_{n=0,1,\dots}$ . The functor  $S: \mathbf{Top} \rightarrow \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$  is both free and acyclic. Acyclicity is clear since  $\Delta^n$  is contractible for all  $n$ .

To see freeness, note that the singleton

$$\{\text{id}_{\Delta^n} : \Delta^n \rightarrow \Delta^n\}$$

forms a basis for  $F_n$  because the abelian group  $S_n(X)$  is free with generating set

$$\{S(\alpha)(\text{id}_{\Delta^n}) = \alpha\}_{\alpha \in \text{Hom}(\Delta^n, X)}.$$

The freeness condition can be interpreted as telling us that in order to know how the functor  $F$  behaves on any object, it is enough to know how it behaves on the  $M_\alpha$ .

**Theorem 17** (acyclic model theorem). Let  $(\mathcal{C}, \mathcal{M})$  be a category with models, and let  $F, G$  be functors  $\mathcal{C} \rightarrow \mathbf{Ch}_{\geq 0}(R\text{-Mod})$  such that  $F$  is free on  $\mathcal{M}$  and  $G$  is acyclic on  $\mathcal{M}$ .

1. Any natural transformation  $\bar{\tau}_0 : H_0(F) \rightarrow H_0(G)$  can be extended to a natural chain map  $\tau : F \rightarrow G$ .
2. This extension is unique up to homotopy in the sense that two natural chain maps  $\tau, \tau' : F \rightarrow G$  inducing the same natural transformation  $H_0(F) \rightarrow H_0(G)$  are naturally chain homotopic.

*Proof.*

1. Let  $\tau : F \Rightarrow G$  be a natural transformation. First, we collect some results about the natural transformation  $\tau_q : F_q \Rightarrow G_q$ . Note that, since

$$F_q(X) \cong R\{F_q(f)(m_j)\}_{j \in J_q, f \in \text{Hom}(M_j, X)}$$

we can specify  $\tau_q(X)$  (the component of  $\tau_q$  at  $X$ ) completely by specifying how it acts on those elements of  $F_q(X)$  of the form  $F_q(f)(m_j)$ , and that we are free in choosing this action.

Consider the following naturality square for some map  $f : M_j \rightarrow X$ .

$$\begin{array}{ccc}
 F_q(M_j) & \xrightarrow{\tau_q(m_j)} & G_q(M_j) \\
 \downarrow F_q(f) & & \downarrow G_q(f) \\
 & \begin{array}{ccc} m_j & \xrightarrow{\quad} & \tau_q(M_j)(m_j) \\ \downarrow & & \downarrow \\ F_q(f)(m_j) & \xrightarrow{\quad} & \star \end{array} & \\
 F_q(X) & \xrightarrow{\tau_q(X)} & G_q(X)
 \end{array}$$

Naturality requires that

$$\tau_q(X)(F(f)(m_j)) = G_q(f)(\tau_q(M_j)(m_j)).$$

Thus, in order to define  $\tau_q(X)$  for all  $X$ , we need only specify how  $\tau_q(M_j)$  behaves on  $m_j \in F_q(M_j)$ . Defining it in this way and extending it by naturality will ensure that the maps we construct form the components of a natural transformation.

For  $q = 0$ , this is easy, since we have a natural transformation  $\bar{\tau}_0$ . Since everything in  $H_0(F)$  is a cycle, we can define  $\tau_0(M_j)(m_j)$  to be any representative of the equivalence class

$$\bar{\tau}_0(M_j)[m_j] \in H_0(G(M_j)).$$

Now suppose we have defined natural transformations  $\tau_{q-1}$ , for  $q > 0$ . For  $j \in J_q$ , we define  $\tau_q(M_j(m_j))$  by

$$\partial \tau_q(M_j)(m_j) = \tau_{q-1}(M_j(\partial m_j)).$$

This is well-defined precisely because

$$\partial \tau_{q-1}(M_j)(\partial m_j) = \tau_{q-2}(\partial^2 m_j) = 0$$

since  $\tau_{q-1}$  is by assumption a chain map and  $G$  is by assumption acyclic on  $\mathcal{M}$ .

2. One defines a chain homotopy inductively using the same trick.

□

## 1.4 Homotopy equivalence

We would like that two maps which are homotopic induce the same maps on homology. As alluded to in Section ??, we will see that a homotopy  $H$  between maps  $f, g: X \rightarrow Y$  induces a chain homotopy  $h$  between  $S_n(f)$  and  $S_n(g)$ .

### 1.4.1 Homotopy invariance: with acyclic models

**Proposition 18.** Let  $f, g: X \rightarrow Y$  be continuous maps between topological spaces, and let  $H: X \times [0, 1] \rightarrow Y$  be a homotopy between them. Then  $H$  induces a homotopy between  $C(f)$  and  $C(g)$ .

*Proof.* Suppose we are given a homotopy  $f \stackrel{H}{\sim} g$ .

$$\begin{array}{ccc}
 X & & \\
 \text{id} \times \{0\} \downarrow & \searrow f & \\
 X \times I & \xrightarrow{H} & X \\
 \text{id} \times \{1\} \uparrow & \nearrow g & \\
 X & & 
 \end{array}$$

Consider the functors

$$F = S_{\bullet}(-), \quad G = S_{\bullet}(I \times -): \mathbf{Top} \rightarrow \mathbf{Ch}_{\geq 0}(\mathbf{Ab}).$$

Take  $\mathbf{Top}$  with models  $\mathcal{M} = \{\Delta^q \mid q = 0, 1, \dots\}$ ,  $J_n = \{*\}$ ,  $\mathcal{M}_{J_n} = \{\Delta^n\}$  and  $m_* = \text{id}_{\Delta^n}$ . For all  $n$ , we have that  $F$  is free because

$$S_n(X) \cong \mathbb{Z}\{S_n(\alpha)(\text{id}_{\Delta^n}) \mid \alpha \in \text{Hom}(\Delta^n, X)\},$$

and that  $G$  is acyclic because  $\Delta^n \times I$  is contractible for all  $n$ .

Denote by  $\iota_X^0$  the map  $X \rightarrow X \times I$ , which sends  $x \mapsto (x, 0)$ . Define  $\iota_X^1$  analogously.

Consider the natural transformations

$$i^0, i^1 : F \Rightarrow G$$

with components

$$i_X^0 = S_{\bullet}(\iota_X^0), \quad i_X^1 = S_{\bullet}(\iota_X^1).$$

These clearly agree on  $H_0$ . Thus, by [Theorem 17](#),  $i^0$  and  $i^1$  are chain homotopic via some chain homotopy  $D$ .

If  $D$  is homotopy between  $i^0$  and  $i^1$ , then  $S(H) \circ D$  is a homotopy between  $S(H) \circ i^0$  and  $S(H) \circ i^1$ . But  $S(H) \circ i^0 = S(f)$ , and  $S(H) \circ i^1 = S(g)$ .  $\square$

**Corollary 19.** Any two topological spaces which are homotopy equivalent have the same homology groups.

**Example 20.** Any contractible space is homotopy equivalent to the one point space  $\text{pt.}$ . Thus, for any contractible space  $X$  we have

$$H_n(X) = \begin{cases} \mathbb{Z}, & n = 0 \\ 0, & n \neq 0 \end{cases}$$

### 1.4.2 Homotopy-invariance: without acyclic models

Such a homotopy  $H$  is a map

$$H: X \times [0, 1] \rightarrow Y.$$

It seems reasonable that we would get the chain homotopy in question by relating the singular homology of  $X$  and the singular homology of  $X \times [0, 1]$ .

Here is the game plan.

- We notice that there are  $n$  obvious ways of mapping

$$p_i: \Delta^{n+1} \rightarrow \Delta^n \times [0, 1],$$

and  $\Delta^n \times [0, 1]$  is the union of the images, which overlap only along their boundaries.

- Given an  $n$ -simplex  $\alpha: \Delta^n \rightarrow X$ , we can produce an  $(n + 1)$ -simplex in  $X \times [0, 1]$  by pulling back:

$$P_i: \Delta^{n+1} \rightarrow \Delta^n \times [0, 1] \rightarrow X \times [0, 1].$$

- Given a homotopy

$$H: X \times [0, 1] \rightarrow Y$$

between  $f$  and  $g$ , we can pull back by the  $P_i$ , giving us an  $(n + 1)$ -simplex

$$P_i(\alpha): \Delta^{n+1} \rightarrow \Delta^n \times [0, 1] \rightarrow X \times [0, 1] \rightarrow Y.$$

The association

$$\alpha \mapsto P_i \alpha$$

is a homomorphism.

- If we take a sum of the  $P_i \alpha$ , we get a cellular decomposition of the image of  $\alpha$ . However, by taking an alternating sum

$$P = \sum_{i=0}^n P_i$$

we can get (upon passing to boundaries) the interior walls to cancel each other out. Thus, the composition

$$d \circ P$$

gives a cellular decomposition of the boundary of the image of the cylinder. The composition  $P \circ d$  gives you a cellular decomposition of the sides of the cylinder with the opposite sign. Thus, the sum  $d \circ P + P \circ d$  gives you the (difference of) the top and the bottom of the cylinder.

- This tells us that *homotopic maps between topological spaces induce the same map*

between homotopy groups.

**Definition 21** (prism maps). The  $i$ th prism map is the map

$$p_i: \Delta^{n+1} \rightarrow \Delta^n \times I; \quad (t_0, \dots, t_{n+1}) \mapsto \left( (t_0, \dots, t_i + t_{i+1}, \dots, t_n), \sum_{j=i+1}^n t_j \right)$$

The  $i$ th prism map sends the vertices  $\{0, \dots, n+1\} \in \Delta^n$  to the vertices of the prism as follows.

$$\begin{array}{ccccccc} 0 & 1 & 2 & \cdots & i & i+1 & \cdots & n+1 \\ \downarrow & \downarrow & \downarrow & & \downarrow & \downarrow & & \downarrow \\ (0, 0) & (1, 0) & (2, 0) & \cdots & (i, 0) & (i, 1) & \cdots & (n, 1) \end{array}$$

We will denote the vertex  $(j, 0)$  by  $a_j$  and  $(j, 1)$  by  $b_j$ . We can thus summarize the situation by saying that

$$p_i: (0, \dots, n+1) \rightarrow (a_1, \dots, a_i, b_i, \dots, b_n),$$

where the  $i$ th element of the last tuple corresponds to the location of the  $i$ th vertex in the prism  $\Delta^n \times I$ .

**Definition 22** (prism operator). We define maps

$$P_i: S_n(X) \rightarrow S_{n+1}(X \times I)$$

which send  $\alpha: \Delta^n \rightarrow X$  to the composition

$$\Delta^{n+1} \xrightarrow{p_i} \Delta^n \times I \xrightarrow{\alpha \times \text{id}_I} X \times I.$$

The prism operator is the alternating sum

$$\sum_{i=0}^n P_i: S_n(X) \rightarrow S_{n+1}(X \times I).$$

Given an  $n$ -simplex  $\sigma$ , the prism operator  $P_i$  creates an  $n+1$ -simplex  $(\alpha \times \text{id}) \circ p_i$ . To keep track of the indices of the  $n+1$ -simplex we are using, we notate this by

$$(\sigma \times \text{id})|_{[a_0, \dots, a_i, b_i, \dots, b_n]}.$$

**Proposition 23.** Denote by  $j_i$ , for  $i = 0, 1$ , the map

$$j_i: X \rightarrow X \times I; \quad x \mapsto (x, i).$$

The prism operator is a chain homotopy between  $S_\bullet(j_0)$  and  $S_\bullet(j_1)$ .

*Proof.* We □

## 1.5 Relative homology

### 1.5.1 Relative homology

Denote by **Pair** the category whose objects are pairs  $(X, A)$ , where  $X$  is a topological space and  $A \hookrightarrow X$  is a subspace, and whose morphisms  $(X, A) \rightarrow (Y, B)$  are maps  $f: X \rightarrow Y$  such that  $f(A) \subset B$ . That is, the category **Pair** is the full subcategory on the category  $\mathbf{Fun}(I, \mathbf{Top})$  on monomorphisms; the objects are diagrams

$$A \hookrightarrow X$$

and the morphisms are commuting squares

$$\begin{array}{ccc} A & \hookrightarrow & X \\ \downarrow & & \downarrow \\ B & \hookrightarrow & Y \end{array}$$

**Definition 24** (relative homology). Let  $(X, A)$  be a pair of spaces. The inclusion  $i: A \hookrightarrow X$  induces a map of chain complexes  $A \hookrightarrow X$ . The relative chain complex of  $(X, A)$  is the cokernel of  $C_\bullet(i)$ .

Since colimits are computed level-wise, the relative chain complex is given by the level-wise quotient

$$S_\bullet(X, A) = S_\bullet(X)/S_\bullet(A).$$

The relative homology of  $(X, A)$  is

$$H_n(X, A) = H_n(S_\bullet(X, A)).$$

**Lemma 25.** For each  $n$ , relative homology provides a functor  $H_n: \mathbf{Pair} \rightarrow \mathbf{Ab}$ .

*Proof.* Consider the following diagram

$$\begin{array}{ccc} S(X)_\bullet & \xrightarrow{f} & S(Y)_\bullet \\ \downarrow & & \downarrow \\ S(X)_\bullet/S(A)_\bullet & \dashrightarrow & S(Y)_\bullet/S(B)_\bullet \end{array}$$

The dashed arrow is uniquely well-defined because of the assumption that  $f(A) \subset B$ , meaning that the relative homology construction is well-defined on the level of the relative chain complex. Functoriality of the relative homology now follows from the

functoriality of  $H_n$ . □

### 1.5.2 The long exact sequence on a pair of spaces

**Proposition 26.** Let  $(X, A)$  be a pair of spaces. There is the following long exact sequence.

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{j+1}(X, A) \\
 & \swarrow & & \searrow & & & \uparrow \delta \\
 & & H_j(A) & \longrightarrow & H_j(X) & \longrightarrow & H_j(X, A) \\
 & \swarrow & & \searrow & & & \uparrow \delta \\
 & & H_{j-1}(A) & \longrightarrow & \cdots & & 
 \end{array}$$

*Proof.* This is the long exact sequence associated to the following short exact sequence.

$$0 \longrightarrow C_\bullet(A) \hookrightarrow C_\bullet(X) \twoheadrightarrow C_\bullet(X, A) \longrightarrow 0$$

□

**Example 27.** Let  $X = \mathbb{D}^n$ , the  $n$ -disk, and  $A = \mathbb{S}^{n-1}$  its boundary  $n$ -sphere.

Consider the long exact sequence on the pair  $(\mathbb{D}^n, \mathbb{S}^{n-1})$ .

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{j+1}(\mathbb{D}^n, \mathbb{S}^{n-1}) \\
 & \swarrow & & \searrow & & & \uparrow \delta \\
 & & H_j(\mathbb{S}^{n-1}) & \longrightarrow & H_j(\mathbb{D}^n) & \longrightarrow & H_j(\mathbb{D}^n, \mathbb{S}^{n-1}) \\
 & \swarrow & & \searrow & & & \uparrow \delta \\
 & & H_{j-1}(\mathbb{S}^{n-1}) & \longrightarrow & \cdots & & 
 \end{array}$$

We know that  $H_j(\mathbb{D}^n) = 0$  for  $n > 0$  because it is contractible. Thus, exactness forces

$$H_j(\mathbb{D}^n, \mathbb{S}^{n-1}) \cong H_{j-1}(\mathbb{S}^{n-1})$$

for  $j > 1$  and  $n \geq 1$ .

**Proposition 28.** Suppose  $i: A \hookrightarrow X$  is a weak retract, i.e. that there is an  $r: X \rightarrow A$  such that  $r \circ i = \text{id}_A$ .

$$\begin{array}{ccccc}
 A & \xhookrightarrow{i} & X & \twoheadrightarrow{r} & A \\
 & & \searrow & \nearrow & \\
 & & \text{id}_A & & 
 \end{array}$$

Then

$$H_n(X) \cong H_n(A) \oplus H_n(X, A).$$

## 1 Homology

*Proof.* Applying the functor  $H_n$  to the diagram above, we find that

$$H_n(r) \circ H_n(i) = \text{id}_{H_n(A)},$$

implying that  $H_n(i)$  is injective. Consider the long exact sequence on the pair  $(X, A)$ .

$$\begin{array}{ccccccc} & & & \cdots & \longrightarrow & H_{n+1}(X, A) & \\ & \swarrow & & & & \searrow & \\ & & \delta & & & & \\ & \swarrow & & & & \searrow & \\ H_n(A) & \xrightarrow{H_n(i)} & H_n(X) & \longrightarrow & H_n(X, A) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ & \swarrow & & & & \searrow & \\ H_{n-1}(A) & \xrightarrow{H_{n-1}(i)} & \cdots & & & & \end{array}$$

The injectivity of  $H_n(i)$  implies that the connecting homomorphisms are zero, meaning that the following sequence is short exact for all  $n$ .

$$0 \longrightarrow H_n(A) \xrightarrow{H_n(i)} H_n(X) \longrightarrow H_n(X, A) \longrightarrow 0$$

As  $H_n(r)$  is a left inverse to  $H_n(i)$ , the sequence above splits from the left, implying by the splitting lemma (Lemma ??) the result.  $\square$

**Proposition 29.** Let  $i: A \rightarrow X$  be a deformation retract,<sup>1</sup> i.e. that there is a homotopy

$$R: X \times [0, 1] \rightarrow X$$

such that the following conditions are satisfied.

1.  $R(x, 0) = x$  for all  $x \in X$
2.  $R(x, 1) \in A$  for all  $x \in X$
3.  $R(a, 1) = a$  for all  $a \in A$

Then  $H_n(i): H_n(A) \rightarrow H_n(X)$  is an isomorphism.

*Proof.* Let

$$r = R(-, 1): X \rightarrow A.$$

Then 3. implies that  $r \circ i = \text{id}_A$ .

Furthermore,  $R(x, -)$  provides a homotopy between  $i \circ r$  and  $\text{id}_X$ . Thus,  $X$  and  $A$  are homotopy equivalent, and  $H_n(i)$  is an isomorphism.  $\square$

**Corollary 30.** If  $i: X \rightarrow A$  is a deformation retract, then  $H_n(X, A) = 0$  for all  $n$ .

<sup>1</sup>I believe we only need  $i$  to be a homotopy equivalence; a deformation retract is a homotopy equivalence in which one of the two homotopies is an identity.

### 1.5.3 The braided monstrosity on a triple of spaces

**Definition 31** (triple of spaces). Let  $X$  be a topological space, and let  $B \subset A \subset X$  be subspaces. We call  $(X, A, B)$  a triple.

A triple of spaces is in particular three pairs of spaces:  $(X, A)$ ,  $(X, B)$ , and  $(A, B)$ . All of these have associated long exact sequences. There is also a fourth long exact sequence.

**Proposition 32.** There is a long exact sequence

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{j+1}(A, B) \\
 & & & & & & \downarrow \delta \\
 & & & & & & H_j(A, B) \longrightarrow H_j(X, B) \longrightarrow H_j(X, A) \\
 & & & & & & \downarrow \delta \\
 & & & & & & H_{j-1}(A, B) \longrightarrow \cdots
 \end{array}$$

*Proof.* This comes from the short exact sequence

$$0 \longrightarrow S_n(A)/S_n(B) \hookrightarrow S_n(X)/S_n(B) \twoheadrightarrow S_n(X)/S_n(A) \longrightarrow 0.$$

9

We can put all four of these together in the following handsome commutative diagram.

## 1.6 Barycentric subdivision

**Definition 33** (cone maps). Let  $v \in \Delta^p$  be a point, and let  $\alpha: \Delta^n \rightarrow \Delta^p$  be a singular  $n$ -simplex. The cone of  $\alpha$  with respect to  $v$  is

$$K_v(\alpha): \Delta^{n+1} \rightarrow \Delta^p$$

defined by sending

$$(t_0, \dots, t_n) \mapsto \begin{cases} (1 - t_{n+1}) \alpha\left(\frac{t_0}{1-t_{n+1}}, \dots, \frac{t_n}{1-t_{n+1}}\right) + t_{n+1}v, & t_{n+1} < 1 \\ v, & t_{n+1} = 1. \end{cases}$$

This is well-defined and continuous.

We extend  $K_v$  linearly to  $S_\bullet(\Delta^p)$ .

**Lemma 34.** The map  $K_v: S_n(\Delta^p) \rightarrow S_{n+1}(\Delta^p)$  satisfies the following identities.

1. For a zero-simplex  $c \in S_0(\Delta^p)$ , we have

$$\partial K_v(c) = \epsilon(c)\kappa_v - c,$$

where  $\kappa_v(e_0) = v$ , and  $\epsilon: S_0(\Delta^p) \rightarrow \mathbb{Z}$  is the augmentation map.

2. For  $n > 0$ , we have the equality

$$\partial \circ K_v - K_v \circ \partial = (-1)^{n+1} \text{id}$$

*Proof.*

1. It suffices to show the claim on generators, i.e. singular 0-simplices  $\Delta^0 \rightarrow \Delta^p$ . Let  $\alpha: \Delta^0 \rightarrow \Delta^p$ . Then  $\epsilon(\alpha) = 1$ , and

$$\begin{aligned} \partial K_v(\alpha)(e_0) &= \partial_0 K_v(\alpha)(e_0) - \partial_1 K_v(\alpha)(e_0) \\ &= \kappa_v(\alpha)(d_0 e_0) - \kappa_v(\alpha)(d_1 e_0) \\ &= \kappa_v(\alpha)(e_1) - \kappa_v(\alpha)(e_0) \\ &= v - \alpha(e_0) \end{aligned}$$

2. An easy calculation shows that

$$\partial_i K_v(\alpha) = \kappa_v(\partial_i \alpha), \quad i < n+1,$$

and

$$\partial_{n+1} K_v(\alpha) = \alpha.$$

Thus,

$$\partial K_v - K_v \partial = (-1)^{n+1} \text{id}$$

as required. □

We first define *Barycentric subdivision* on models  $\{\Delta^n\}$ : it is a chain map

$$B: S_\bullet(\Delta^p) \rightarrow S_\bullet(\Delta^p)$$

defined on an 0-simplex  $\alpha: \Delta^0 \rightarrow \Delta^p$  by

$$B(\alpha) = \alpha,$$

and for  $\sigma: \Delta^n \rightarrow \Delta^p$  inductively by

$$B(\sigma) = (-1)^n (K_v)(B(\partial \sigma)).$$

This is a bona-fide chain map because...

Since the functor  $S_\bullet$  is  $\{\Delta^n\}$ -free, we can extend  $B$  to a natural chain map  $S_\bullet \rightarrow S_\bullet$  via

$$B_X(\alpha) = S_n(\alpha)(B_{\Delta^n}(\text{id}_{\Delta^n})), \quad \alpha: \Delta^n \rightarrow X.$$

**Theorem 35.** The chain map  $B: S_\bullet(X)$  is chain homotopic to the identity.

*Proof.* For a zero-simplex  $\alpha: \Delta^0 \rightarrow X$

$$\begin{aligned} B_X(\alpha) &= S_0(\alpha)(B_{\Delta^0}(\text{id}_{\Delta^0})) \\ &= S_0(\alpha)(\text{id}_{\Delta^0}) \\ &= \alpha, \end{aligned}$$

so  $B$  and  $\text{id}_{S_\bullet}$  agree on  $H_0(S_\bullet)$ . The claim follows from [Theorem 17](#). □

Let  $X$  be a topological space, and let  $\mathfrak{U} = \{U_i \mid i \in I\}$  be an open cover of  $X$ . Denote by

$$S_n^{\mathfrak{U}}(X)$$

the free group generated by those continuous functions

$$\alpha: \Delta^n \rightarrow X$$

whose images are completely contained in some open set in the open cover  $\mathfrak{U}$ . That is, such that there exists some  $i$  such that  $\alpha(\Delta^n) \subset U_i$ . The inclusion  $S_n^{\mathfrak{U}}(X) \hookrightarrow S_n(X)$

## 1 Homology

induces a chain structure on  $S_{\bullet}^{\mathfrak{U}}(X)$ .

$$\begin{array}{ccccccc} \cdots & \longrightarrow & S_2^{\mathfrak{U}}(X) & \longrightarrow & S_1^{\mathfrak{U}}(X) & \longrightarrow & S_0^{\mathfrak{U}}(X) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \longrightarrow & S_2(X) & \longrightarrow & S_1(X) & \longrightarrow & S_0(X) \longrightarrow 0 \end{array}$$

**Fact 36.** For any open cover  $\mathfrak{U}$  of a topological space  $X$ , for every simplex  $\alpha: \Delta^n \rightarrow X$ , there exists some  $n \geq 0$  such that  $B^n \alpha \in S^{\mathfrak{U}}(X)$ .

*Sketch of proof.* This is really just some messing with Lebesgue numbers. One first shows that for any *affine simplex*<sup>2</sup>  $\alpha: \Delta^n \rightarrow \Delta^p$ ,

$$\max_{\sigma} \text{diam}(\sigma) \leq \left( \frac{n}{n+1} \right)^k \text{diam}(\alpha),$$

where  $\sigma$  runs over all simplices in  $B^k \alpha$ . Thus, for any  $n$ ,

$$\lim_{k \rightarrow \infty} \max \text{diam}(B^k \alpha) = 0.$$

*Lebesgue's number lemma* tells us that for any compact metric space  $X$  and any open cover  $\mathfrak{U} = \{U_i\}$  of  $X$ , there is some  $\delta > 0$  such that any subset  $S \subset X$  with  $\text{diam}(S) < \delta$  is completely contained in some  $U_i$ .

Now let  $X$  be any topological space, and let  $\alpha: \Delta^n \rightarrow X$ . Let  $\mathfrak{U}$  be an open cover of  $X$ . Then the preimages of the open cover under  $\alpha$  form an open cover of  $\Delta^n$ . Since  $\Delta^n$  is a compact metric space, Lebesgue's number lemma tells us that there exists  $k \geq 0$  such that every simplex in  $B^k \text{id}_{\Delta^n}$  is completely contained in the preimage of at least one of the  $U_i \in \mathfrak{U}$ . Mapping everything forward with  $S_{\bullet}(\alpha)$  gives us the result we want.  $\square$

We have proved the following.

**Corollary 37.** Every chain in  $S_n(X)$  is homologous to a chain in  $S^{\mathfrak{U}}(X)$

**Proposition 38.** There is a natural homotopy equivalence  $S_{\bullet}^{\mathfrak{U}} \cong S_{\bullet}$ .

**Corollary 39.**

$$H_n(X) \cong H_n^{\mathfrak{U}}(X).$$

This fact allows us almost immediately to read of two important theorems.

---

<sup>2</sup>I.e. a singular simplex which comes from an affine map  $\mathbb{R}^{n+1} \rightarrow \mathbb{R}^{p+1}$

### 1.6.1 Excision

**Theorem 40** (excision). Let  $W \subset A \subset X$  be a triple of topological spaces such that  $\bar{W} \subset \mathring{A}$ . Then the right-facing inclusions

$$\begin{array}{ccc} A \setminus W & \xhookrightarrow{i} & A \\ \downarrow & & \downarrow \\ X \setminus W & \xhookrightarrow{i} & X \end{array}$$

induce an isomorphism

$$H_n(i): H_n(X \setminus W, A \setminus W) \cong H_n(X, A).$$

*Proof.* Consider the open cover  $\mathfrak{U} = (\mathring{A}, X \setminus \bar{W})$  of  $X$ .

First, we show that  $H_n(i)$  is surjective. Let  $c \in S_n(X, A)$  be a relative cycle. By [Corollary 37](#), we can replace (not uniquely, but who cares)  $c$  by a homologous sum  $c' + c''$  with  $c' \in S_n(\mathring{A})$  and  $c'' \in S_n(X \setminus \bar{W})$ .

NOTE: THIS IS WRONG. NEED TO FIX.

But  $c' \sim 0$  in  $H_n(X, A)$ , so we have found  $c \sim c''$ , with  $c'' \in S_n(X \setminus \bar{W})$ .

Now we compute a boundary:

$$\partial c \sim \partial c''.$$

By definition,

$$\partial c'' \in S_{n-1}(X \setminus \bar{W}) \subset S_{n-1}(X \setminus W).$$

However,  $c'' \in S_{n-1}(A)$ , so

$$c'' \in S_{n-1}(X \setminus W) \cap S_{n-1}(A) = S_{n-1}(A \setminus W).$$

Therefore,  $c$  is homologous to a relative cycle in  $S_n(X \setminus W, A \setminus W)$ .

Now we show that  $H_n(i)$  is injective. Suppose that  $c \in S_n(X \setminus W)$  such that  $\partial c \in S_n(A \setminus W)$ .

Further suppose that  $H_n(i)[c] = 0$ , i.e. that we can write

$$i(c) = \partial b + a'$$

with  $b \in S_{n+1}(X)$  and  $a' \in S_n(A)$ . Then  $i(c)$  is homologous to  $\square$

That is, when considering relative homology  $H_n(X, A)$ , we may cut away a subspace from the interior of  $A$  without harming anything. This gives us a hint as to the interpretation of relative homology:  $H_n(X, A)$  can be interpreted the part of  $H_n(X)$  which does not come from  $A$ .

### 1.6.2 The Mayer-Vietoris sequence

**Theorem 41** (Mayer-Vietoris). Let  $X$  be a topological space, and let  $\mathcal{U} = \{X_1, X_2\}$  be an open cover of  $X$ , i.e. let  $X = X_1 \cup X_2$ . Then we have the following long exact sequence.

$$\begin{array}{ccccccc}
 & & & \dots & \longrightarrow & H_{n+1}(X) & \\
 & \swarrow & & \delta & \searrow & & \\
 H_n(X_1 \cap X_2) & \longrightarrow & H_n(X_1) \oplus H_n(X_2) & \longrightarrow & H_n(X) & & \\
 & \swarrow & & \delta & \searrow & & \\
 H_{n-1}(X_1 \cap X_2) & \longrightarrow & \dots & & & & 
 \end{array}$$

*Proof.* We can draw our inclusions as the following pushout.

$$\begin{array}{ccccc}
 & & X_1 & & \\
 & \nearrow i_1 & & \searrow \kappa_1 & \\
 X_1 \cap X_2 & & & & X \\
 & \searrow i_2 & & \nearrow \kappa_2 & \\
 & & X_2 & & 
 \end{array}$$

We have, almost by definition, the following short exact sequence.

$$0 \longrightarrow S_\bullet(X_1 \cap X_2) \xrightarrow{(i_1, i_2)} S_\bullet(X_1) \oplus S_\bullet(X_2) \xrightarrow{\kappa_1 - \kappa_2} S_\bullet^{\mathcal{U}}(X) \longrightarrow 0$$

This gives the following long exact sequence on homology.

$$\begin{array}{ccccccc}
 & & & \dots & \longrightarrow & H_{n+1}^{\mathcal{U}}(X) & \\
 & \swarrow & & \delta & \searrow & & \\
 H_n(X_1 \cap X_2) & \longrightarrow & H_n(X_1) \oplus H_n(X_2) & \longrightarrow & H_n^{\mathcal{U}}(X) & & \\
 & \swarrow & & \delta & \searrow & & \\
 H_{n-1}(X_1 \cap X_2) & \longrightarrow & \dots & & & & 
 \end{array}$$

We have seen that  $H_n^{\mathcal{U}}(X) \cong H_n(X)$ ; the result follows.  $\square$

**Example 42** (Homology groups of spheres). We can decompose  $\mathbb{S}^n$  as

$$\mathbb{S}^n = (\mathbb{S}^n \setminus N) \cup (\mathbb{S}^n \setminus S),$$

where  $N$  and  $S$  are the North and South pole respectively. This gives us the following

pushout.

$$\begin{array}{ccccc}
 & & \mathbb{S}^n \setminus N & & \\
 & \nearrow & & \searrow & \\
 (\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S) & & & & \mathbb{S}^n \\
 & \searrow & & \nearrow & \\
 & & \mathbb{S}^n \setminus S & &
 \end{array}$$

The Mayer-Vietoris sequence is as follows.

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{j+1}(\mathbb{S}^n) \\
 & & & & & \searrow \delta & \nearrow \\
 & & & & H_j((\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S)) & \longrightarrow & H_j(\mathbb{S}^n \setminus N) \oplus H_j(\mathbb{S}^n \setminus S) \longrightarrow H_j^{\text{ul}}(X) \\
 & & & & \searrow \delta & \nearrow \\
 & & & & H_{j-1}((\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S)) & \longrightarrow & \cdots
 \end{array}$$

We know that

$$\mathbb{S}^n \setminus N \cong \mathbb{S}^n \setminus S \cong \mathbb{D}^n \simeq \text{pt}$$

and that

$$(\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S) \cong I \times \mathbb{S}^{n-1} \simeq \mathbb{S}^{n-1},$$

so using the fact that homology respects homotopy, the above exact sequence reduces (for  $j > 1$ ) to

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{j+1}(\mathbb{S}^n) \\
 & & & & & \searrow \delta & \nearrow \\
 & & & & H_j(\mathbb{S}^{n-1}) & \longrightarrow & 0 \longrightarrow H_j(\mathbb{S}^n) \\
 & & & & \searrow \delta & \nearrow \\
 & & & & H_{j-1}(\mathbb{S}^{n-1}) & \longrightarrow & \cdots
 \end{array}$$

Thus, for  $i > 1$ , we have

$$H_i(\mathbb{S}^j) \cong H_{i-1}(\mathbb{S}^{j-1}).$$

We have already noted the following facts.

- $H_0$  counts the number of connected components, so

$$H_0(\mathbb{S}^j) = \begin{cases} \mathbb{Z} \oplus \mathbb{Z}, & j = 0 \\ \mathbb{Z}, & j > 0 \end{cases}$$

## 1 Homology

- For path connected  $X$ ,  $H_1(X) \cong \pi_1(X)_{\text{ab}}$ , so

$$H_1(\mathbb{S}^j) = \begin{cases} \mathbb{Z}, & j = 0 \\ 0, & \text{otherwise} \end{cases}$$

- For  $i > 0$ ,  $H_i(\text{pt}) = 0$ , so  $H_i(\mathbb{S}^0) = 0$ .

This gives us the following table.

|                     |                                |              |         |         |
|---------------------|--------------------------------|--------------|---------|---------|
| $j = 3$             | $\mathbb{Z}$                   | 0            |         |         |
| $j = 2$             | $\mathbb{Z}$                   | 0            |         |         |
| $j = 1$             | $\mathbb{Z}$                   | $\mathbb{Z}$ |         |         |
| $j = 0$             | $\mathbb{Z} \oplus \mathbb{Z}$ | 0            | 0       | 0       |
| $H_i(\mathbb{S}^j)$ | $i = 0$                        | $i = 1$      | $i = 2$ | $i = 3$ |

The relation

$$H_i(\mathbb{S}^j) \cong H_{i-1}(\mathbb{S}^{j-1}), \quad i > 1$$

allows us to fill in the above table as follows.

|                     |                                |              |              |              |
|---------------------|--------------------------------|--------------|--------------|--------------|
| $j = 3$             | $\mathbb{Z}$                   | 0            | 0            | $\mathbb{Z}$ |
| $j = 2$             | $\mathbb{Z}$                   | 0            | $\mathbb{Z}$ | 0            |
| $j = 1$             | $\mathbb{Z}$                   | $\mathbb{Z}$ | 0            | 0            |
| $j = 0$             | $\mathbb{Z} \oplus \mathbb{Z}$ | 0            | 0            | 0            |
| $H_i(\mathbb{S}^j)$ | $i = 0$                        | $i = 1$      | $i = 2$      | $i = 3$      |

(1.1)

**Example 43.** Above, we used the Hurewicz homomorphism to see that

$$H_1(\mathbb{S}^j) = \begin{cases} \mathbb{Z}, & j = 1 \\ 0, & \text{otherwise} \end{cases}.$$

We can also see this directly from the Mayer-Vietoris sequence. Recall that we expressed  $\mathbb{S}^n$  as the following pushout, with  $X^+ \cong X^- \simeq \mathbb{D}^n$ .

$$\begin{array}{ccc} & X^+ & \\ \nearrow & & \searrow \\ X^+ \cap X^- & & \mathbb{S}^n \\ \searrow & & \nearrow \\ & X^- & \end{array}$$

Also recall that with this setup, we had  $X^+ \cap X^- \simeq \mathbb{S}^{n-1}$ .

First, fix  $n > 1$ , and consider the following part of the Mayer-Vietoris sequence.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & 0 & \longrightarrow & H_1(\mathbb{S}^n) & & \\ & & & \searrow \delta & & \nearrow & \\ & H_0(X^+ \cap X^-) & \xrightarrow{H_0(i_0, i_1)} & H_0(X^+) \oplus H_0(X^-) & \longrightarrow & \cdots & \end{array}$$

If we can verify that the morphism  $H_0(i_0, i_1)$  is injective, then we are done, because exactness will force  $H_1(\mathbb{S}^n) \cong 0$ .

The elements of  $H_0(X^+ \cap X^-)$  are equivalence classes of points of  $X^+$  and  $X^-$ , with one equivalence class per connected component. Let  $p \in X^+ \cap X^-$ . Then  $i_0(p)$  is a point of  $X^+$ , and  $i_1(p)$  is a point of  $X^-$ . Each of these is a generator for the corresponding zeroth homology, so  $(i_0, i_1)$  sends the generator  $[p]$  to a the pair  $([i_0(p)], [i_1(p)])$ . This is clearly injective.

Now let  $n = 1$ , and consider the following portion of the Mayer-Vietoris sequence.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & 0 & \longrightarrow & H_1(\mathbb{S}^1) & & \\ & & & & \delta & \searrow & \\ & & & & & & \\ H_0(X^+ \cap X^-) & \xrightarrow{H_0(i_0, i_1)} & H_0(X^+) \oplus H_0(X^-) & \xrightarrow{H_0(\kappa_1) - H_0(\kappa_2)} & H_0(\mathbb{S}^1) & & \end{array}$$

We can immediately replace things we know, finding the following.

$$(a, b) \longmapsto (a + b, a + b)$$

$$0 \longrightarrow H_1(\mathbb{S}^1) \hookrightarrow \mathbb{Z} \oplus \mathbb{Z} \xrightarrow{f} \mathbb{Z} \oplus \mathbb{Z} \longrightarrow \mathbb{Z}$$

$$(c, d) \longmapsto c - d$$

The kernel of  $f$  is the free group generated by  $(a, a)$ . Thus,  $H_1(\mathbb{S}^1) \cong \mathbb{Z}$ .

### 1.6.3 The relative Mayer-Vietoris sequence

**Theorem 44** (relative Mayer-Vietoris sequence). Let  $X$  be a topological space, and let  $A, B \subset X$  open in  $A \cup B$ . Denote  $\mathfrak{U} = \{A, B\}$ .

## 1 Homology

Then there is a long exact sequence

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{n+1}(X, A \cup B) \\
 & \swarrow & & \searrow & & & \delta \\
 & H_n(X, A \cap B) & \longrightarrow & H_n(X, A) \oplus H_n(X, B) & \longrightarrow & H_n(X, A \cup B) & \\
 & \swarrow & & \searrow & & & \delta \\
 & H_{n-1}(X, A \cap B) & \longrightarrow & \cdots & & & 
 \end{array}$$

*Proof.* Consider the following commuting diagram.

$$\begin{array}{ccccccc}
 & 0 & & 0 & & 0 & \\
 & \downarrow & & \downarrow & & \downarrow & \\
 0 & \longrightarrow & S_n(A \cap B) & \longrightarrow & S_n(A) \oplus S_n(B) & \longrightarrow & S_n^{\mathcal{U}}(A \cup B) \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & S_n(X) & \longrightarrow & S_n(X) \oplus S_n(X) & \longrightarrow & S_n(X) \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & S_n(X, A \cap B) & \longrightarrow & S_n(X, A) \oplus S_n(X, B) & \longrightarrow & S_n(X)/S_n^{\mathcal{U}}(A \cup B) \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & 0 & & 0 & & 0
 \end{array}$$

All columns are trivially short exact sequences, as are the first two rows. Thus, the nine lemma (Theorem ??) implies that the last row is also exact.

Consider the following map of short exact sequences; the first row is the last column of the above grid.

$$\begin{array}{ccccccc}
 0 & \longrightarrow & S_n^{\mathcal{U}}(A \cup B) & \hookrightarrow & S_n(X) & \twoheadrightarrow & S_n(X)/S_n^{\mathcal{U}}(A \cup B) \longrightarrow 0 \\
 & & \phi \downarrow & & \parallel & & \downarrow \psi \\
 0 & \longrightarrow & S_n(A \cup B) & \longrightarrow & S_n(X) & \twoheadrightarrow & S_n(X, A \cup B) \longrightarrow 0
 \end{array}$$

This gives us, by Lemma ??, a morphism of long exact sequences on homology.

$$\begin{array}{ccccccc}
 H_n(S_{\bullet}^{\mathcal{U}}(A \cup B)) & \longrightarrow & H_n(X) & \longrightarrow & H_n(S_{\bullet}(X)/S_{\bullet}^{\mathcal{U}}(A \cup B)) & \longrightarrow & H_{n-1}(S_{\bullet}^{\mathcal{U}}(A \cup B)) \longrightarrow H_{n-1}(X) \\
 H_n(\phi) \downarrow & & \parallel & & \downarrow H_n(\psi) & & \downarrow H_{n-1}(\phi) & \parallel \\
 H_n(A \cup B) & \longrightarrow & H_n(X) & \longrightarrow & H_n(X, A \cup B) & \longrightarrow & H_{n-1}(A \cup B) & \longrightarrow H_{n-1}(X)
 \end{array}$$

We have seen (in [Fact 36](#)) that  $H_i(\phi)$  is an isomorphism for all  $i$ . Thus, the five lemma (Theorem ??) tells us that  $H_n(\psi)$  is an isomorphism. Thus, the bottom row of our grid

can be written

$$0 \longrightarrow S_n(X, A \cap B) \hookrightarrow S_n(X, A) \oplus S_n(X, B) \twoheadrightarrow S_n(X, A \cup B) \longrightarrow 0 ,$$

and taking the long exact sequence on homology gives the result.  $\square$

## 1.7 Reduced homology

We have seen that reduced homology  $\tilde{H}_n(X)$  agrees with  $H_n(X)$  in positive degrees, and is missing a copy of  $\mathbb{Z}$  in the zeroth degree. There are three equivalent ways of understanding this: one geometric, one algebraic, and one somewhere in between.

1. **Geometric:** Picking any point  $x \in X$ , one can define the reduced homology of  $X$  by

$$\tilde{H}_n(X) = H_n(X, x).$$

2. **In between:** One can define

$$\tilde{H}_n(X) = \ker(H_n(X) \rightarrow H_n(\text{pt})).$$

3. **Algebraic:** One can augment the singular chain complex  $C_\bullet(X)$  by adding a copy of  $\mathbb{Z}$  in degree  $-1$ , so that

$$\tilde{C}_n(X) = \begin{cases} C_n(X), & n \neq -1 \\ \mathbb{Z}, & n = -1. \end{cases}$$

Then one can define

$$\tilde{H}_n(X) = H_n(\tilde{C}_\bullet).$$

There is a more modern point of view, which is the one we have taken so far. In constructing the singular chain complex of our space  $X$ , we used the following composition.

$$\mathbf{Top} \xrightarrow{\mathbf{Sing}} \mathbf{Set}_\Delta \xrightarrow{\mathcal{F}} \mathbf{Ab}_\Delta \xrightarrow{N} \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$$

For many purposes, there is a more natural category than  $\Delta$  to use: the category  $\bar{\Delta}$ , which includes the empty simplex  $[-1]$ . The functor  $\mathbf{Sing}$  now has a component corresponding to  $(-1)$ -simplices:

$$\mathbf{Sing}(X)_{-1} = \text{Hom}_{\mathbf{Top}}(\rho([-1]), X) = \text{Hom}_{\mathbf{Top}}(\emptyset, X) = \{*\},$$

since the empty topological space is initial in  $\mathbf{Top}$ . Passing through  $\mathcal{F}$  thus gives a copy of  $\mathbb{Z}$  as required. Thus, using  $\bar{\Delta}$  instead of  $\Delta$  gives the augmented singular chain complex.

## 1 Homology

These all have the desired effect, and which method one uses is a matter of preference. To see this, note the following.

- (1  $\Leftrightarrow$  2): Since  $H_n(P)$  is free for all  $n$ , the sequence

$$0 \longrightarrow \ker H_n(\epsilon) \hookrightarrow H_n(X) \twoheadrightarrow H_n(\{x\}) \longrightarrow 0$$

splits, telling us that

$$H_n(X) \cong \ker H_n(\epsilon) \oplus H_n(\{x\}).$$

Applying the functor  $H_n \circ S$  to the diagram

$$\begin{array}{ccccc} \{x\} & \xhookrightarrow{i} & X & \xrightarrow{\epsilon} & \{x\} \\ & & \searrow & \nearrow & \\ & & \text{id}_{\{x\}} & & \end{array}$$

one finds that  $H_n(i)$  is an injection. Therefore, the connecting homomorphisms for the long exact sequence on the pair  $(X, x)$

$$\cdots \longrightarrow H_{n+1}(X, x) \xrightarrow{\delta} H_n(\{x\}) \xhookrightarrow{i} H_n(X) \longrightarrow \cdots$$

must be zero, so the sequence

$$0 \longrightarrow H_n(\{x\}) \xhookrightarrow{i} H_n(X) \twoheadrightarrow H_n(X, x) \longrightarrow 0$$

is exact. Thus,  $H_n(X, x) \cong H_n(X) \oplus H_n(X, x)$ . But

$$H_n(X) \oplus H_n(X, x) \cong H_n(X) \oplus \ker H_n(\epsilon),$$

so  $H_n(X, x) \cong \ker H_n(\epsilon)$ .

- (2  $\Leftrightarrow$  3): Consider the chain map  $S_\bullet(X) \rightarrow S_\bullet(P)$ .

$$\begin{array}{ccccccc} \cdots & \longrightarrow & S_2(X) & \xrightarrow{d_2} & S_1(X) & \xrightarrow{d_1} & S_0(X) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \epsilon \\ \cdots & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} \longrightarrow 0 \end{array}.$$

Considering this as a chain complex

$$\cdots \longrightarrow S_2 \longrightarrow S_1 \longrightarrow S_0 \twoheadrightarrow \mathbb{Z} \longrightarrow 0,$$

the homology  $H_0(S_\bullet(X))$  is given by  $\ker \epsilon / \text{im } d_1$ . But  $d_1$  is epi, so  $H_0(\tilde{C}_\bullet) \cong \ker \epsilon$ .

**Proposition 45.** Relative homology agrees with ordinary homology in degrees greater

than 0, and in degree zero we have the relation

$$H_0(X) \cong \tilde{H}_0(X) \oplus \mathbb{Z},$$

although this isomorphism is not canonical.

*Proof.* Trivial from algebraic definition.  $\square$

### 1.7.1 Deja vu all over again

Many of our results for regular homology hold also for reduced homology.

**Proposition 46.** There is a long exact sequence for a pair of spaces

$$\begin{array}{ccccccc} & & \cdots & \longrightarrow & \tilde{H}_{j+1}(X, A) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ \tilde{H}_j(A) & \longrightarrow & \tilde{H}_j(X) & \longrightarrow & \tilde{H}_j(X, A) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ \tilde{H}_{j-1}(A) & \longrightarrow & \cdots & & & & \end{array}$$

We're now ready to prove quite a nice theorem.

**Proposition 47** (Brouwer). For any  $n \geq 1$ , any continuous bijective map  $f: \mathbb{D}^n \rightarrow \mathbb{D}^n$  has at least one fixed point.

*Proof.* Suppose we have such a map. Then  $x$  and  $f(x)$  are different for all  $x$ , and we can draw a ray starting at  $f(x)$  and passing through  $f(x)$ . This ray intersects  $\partial\mathbb{D}^n \cong \mathbb{S}^{n-1}$  at exactly one place  $r(x)$ , giving us a map

$$r: \mathbb{D}^n \rightarrow \mathbb{S}^{n-1}; \quad x \mapsto r(x).$$

This is clearly continuous, and it fixes  $\partial\mathbb{D}^n \subset \mathbb{D}^n$ . Thus, we have the following commutative diagram.

$$\begin{array}{ccccc} \mathbb{S}^{n-1} & \xhookrightarrow{\text{incl.}} & \mathbb{D}^n & \xrightarrow{r} & \mathbb{S}^{n-1} \\ & & \searrow & \nearrow & \\ & & \text{id}_{\mathbb{S}^{n-1}} & & \end{array}$$

Applying  $\tilde{H}_n$  gives the following commutative diagram.

$$\begin{array}{ccccc} \tilde{H}_{n-1}(\mathbb{S}^{n-1}) & \xhookrightarrow{\tilde{H}_{n-1}(\text{incl.})} & \tilde{H}_{n-1}(\mathbb{D}^n) & \xrightarrow{\tilde{H}_{n-1}(r)} & \tilde{H}_{n-1}(\mathbb{S}^{n-1}) \\ & & \searrow & \nearrow & \\ & & \text{id}_{\tilde{H}_n(\mathbb{S}^{n-1})} & & \end{array}$$

## 1 Homology

But  $\tilde{H}_{n-1}(\mathbb{S}^{n-1}) \cong \mathbb{Z}$  and  $\tilde{H}_{n-1}(\mathbb{D}^n) \cong 0$  for all  $n \geq 1$ , so  $\tilde{H}_{n-1}(r)$  cannot be surjective.  $\square$

**Proposition 48.** We have a reduced Mayer-Vietoris sequence.

$$\begin{array}{ccccccc}
 & & & \cdots & \longrightarrow & \tilde{H}_{n+1}(X) & \\
 & & & & \searrow & \delta & \nearrow \\
 & \tilde{H}_n(X_1 \cap X_2) & \longrightarrow & \tilde{H}_n(X_1) \oplus \tilde{H}_n(X_2) & \longrightarrow & \tilde{H}_n(X) & \\
 & \nearrow & \delta & \nwarrow & & & \\
 & \tilde{H}_{n-1}(X_1 \cap X_2) & \longrightarrow & \cdots & & & 
 \end{array}$$

**Proposition 49.** Let  $\{(X_i, x_i)\}_{i \in I}$  be a set of pointed topological spaces such that each  $x_i$  has an open neighborhood  $U_i \subset X_i$  of which it is a deformation retract. Then for any finite  $E \subset I^3$  we have

$$\tilde{H}_n\left(\bigvee_{i \in E} X_i\right) \cong \bigoplus_{i \in E} \tilde{H}_n(X_i).$$

*Proof.* We prove the case of two bouquet summands; the rest follows by induction. We know that

$$X_1 \vee X_2 = (X_1 \vee U_2) \cup (U_1 \vee X_2)$$

is an open cover. Thus, the reduced Mayer-Vietoris sequence of [Proposition 48](#) tells us that the following sequence is exact.

$$0 \longrightarrow \tilde{H}_n(X_1) \oplus \tilde{H}_n(X_2) \longrightarrow \tilde{H}_n(X) \longrightarrow 0$$

In particular, for  $n > 0$ , we find that the corresponding sequence on non-reduced homology is exact.

$$0 \longrightarrow H_n(X_1) \oplus H_n(X_2) \longrightarrow H_n(X) \longrightarrow 0$$

$\square$

**Definition 50** (good pair). A pair of spaces  $(X, A)$  is said to be a good pair if the following conditions are satisfied.

1.  $A$  is closed inside  $X$ .
2. There exists an open set  $U$  with  $A \subset U$  such that  $A$  is a deformation retract of  $U$ .

**Proposition 51.** Let  $(X, A)$  be a good pair. Let  $\pi: X \rightarrow X/A$  be the canonical projection. Then

$$H(X, A) \cong \tilde{H}_n(X/A) \quad \text{for all } n \geq 0.$$

<sup>3</sup>This finiteness condition is not actually necessary, but giving it here avoids a colimit argument.

*Proof.* First, note that since  $X \setminus A \cong (X/A) \setminus \{b\}$  and  $U \setminus A \cong (U/A) \setminus \{b\}$ , we have an isomorphism of pairs

$$(X \setminus A, U \setminus A) \cong ((X/A) \setminus \{b\}, (U/A) \setminus \{b\}). \quad (1.2)$$

Thus, we have the following chain of isomorphisms.

$$\begin{aligned} H_n(X, A) &\cong H_n(X, U) && \left( \begin{array}{l} A \text{ deformation} \\ \text{retract of } U \end{array} \right) \\ &\cong H_n(X \setminus A, U \setminus A) && (\text{excision}) \\ &\cong H_n((X/A) \setminus \{b\}, (U/A) \setminus \{b\}) && (\text{Equation 1.2}) \\ &\cong H_n(X/A, U/A) && (\text{excision}) \\ &\cong H_n(X/A, \{b\}) && \left( \begin{array}{l} \{b\} \text{ deformation} \\ \text{retract of } U/A \end{array} \right) \\ &\cong \tilde{H}_n(X/A) \end{aligned}$$

□

**Theorem 52** (suspension isomorphism). Let  $(X, A)$  be a good pair. Then

$$H_n(\Sigma X, \Sigma A) \cong \tilde{H}_{n-1}(X, A), \quad \text{for all } n > 0.$$

## 1.8 Mapping degree

We have shown that

$$\tilde{H}_n(\mathbb{S}^m) \cong \begin{cases} \mathbb{Z}, & n = m \\ 0, & n \neq m \end{cases}.$$

Thus, we may pick in each  $H_n(\mathbb{S}^n)$  a generator  $\mu_n$ . Let  $f: \mathbb{S}^n \rightarrow \mathbb{S}^n$  be a continuous map. Then

$$H_n(f)(\mu_n) = d \mu_n, \quad \text{for some } d \in \mathbb{Z}.$$

**Definition 53** (mapping degree). We call  $d \in \mathbb{Z}$  as above the mapping degree of  $f$ , and denote it by  $\deg(f)$ .

**Example 54.** Consider the map

$$\omega: [0, 1] \rightarrow \mathbb{S}^1; \quad t \mapsto e^{2\pi i t}.$$

The 1-simplex  $\omega$  generates the fundamental group  $\pi_1(\mathbb{S}^1)$ , so by the Hurewicz homomorphism ([Theorem 10](#)), the class  $[\omega]$  generates  $H_1(\mathbb{S}^1)$ . We can think of  $[\omega]$  as  $1 \in \mathbb{Z}$ .

Now consider the map

$$f_n: \mathbb{S}^1 \rightarrow \mathbb{S}^1; \quad x \mapsto x^n.$$

We have

$$\begin{aligned} H_1(f_n)(\omega) &= [f_n \circ \omega] \\ &= [e^{2\pi i n t}]. \end{aligned}$$

The naturality of the Hurewicz isomorphism ([Theorem 10](#)) tells us that the following diagram commutes.

$$\begin{array}{ccc} \pi_1(\mathbb{S}^1)_{\text{ab}} & \xrightarrow{\pi_1(f_n)_{\text{ab}}} & \pi_1(\mathbb{S}^1)_{\text{ab}} \\ h_{\mathbb{S}^1} \downarrow & & \downarrow h_{\mathbb{S}^1} \\ H_1(\mathbb{S}^1) & \xrightarrow{H_1(f_n)} & H_1(\mathbb{S}^1) \end{array}$$

## 1.9 CW Complexes

CW complexes are a class of particularly nicely-behaved topological spaces.

**Definition 55** (cell). Let  $X$  be a topological space. We say that  $X$  is an  $n$ -cell if  $X$  is homeomorphic to  $\mathbb{R}^n$ . We call the number  $n$  the dimension of  $X$ .

**Definition 56** (cell decomposition). A cell decomposition of a topological space  $X$  is a decomposition

$$X = \bigsqcup_{i \in I} X_i, \quad X_i \cong \mathbb{R}^{n_i}$$

where the disjoint union is of sets rather than topological spaces.

**Definition 57** (CW complex). A Hausdorff topological space  $X$ , together with a cell decomposition, is known as a CW complex<sup>4</sup> if it satisfies the following conditions.

(CW1) For every  $n$ -cell  $\sigma \subset X$ , there is a continuous map  $\Phi_\sigma: \mathbb{D}^n \rightarrow X$  such that the restriction of  $\Phi_\sigma$  to  $\mathring{\mathbb{D}}^n$  is a homeomorphism

$$\Phi_\sigma|_{\mathring{\mathbb{D}}^n} \cong \sigma,$$

and  $\Phi_\sigma$  maps  $\mathbb{S}^{n-1} = \partial\mathbb{D}^n$  to the union of cells of dimension of at most  $n - 1$ .

(CW2) For every  $n$ -cell  $\sigma$ , the closure  $\bar{\sigma} \subset X$  has a non-trivial intersection with at most finitely many cells of  $X$ .

(CW3) A subset  $A \subset X$  is closed if and only if  $A \cap \bar{\sigma}$  is closed for all cells  $\sigma \in X$ .

At this point, we define some terminology.

- The map  $\Phi_\sigma$  is called the *characteristic map* of the cell  $\sigma$ .

<sup>4</sup>[Axiom \(CW2\)](#) is called the *closure-finiteness* condition. This is the ‘C’ in CW complex. [Axiom \(CW3\)](#) says that  $X$  carries the *weak topology* and is responsible for the ‘W’.

- Its restriction  $\Phi_\sigma|_{\mathbb{S}^{n-1}}$  is called the *attaching map*.

**Example 58.** Consider the unit interval  $I = [0, 1]$ . This has an obvious CW structure with two 0-cells and one 1-cell. It also has a CW structure with  $n + 1$  0-cells and  $n$  1-cells, which looks like  $n$  intervals glued together at their endpoints.

However, we must be careful. Consider the cell decomposition of the interval with zero-cells

$$\sigma_k^0 = \frac{1}{k} \text{ for } k \in \mathbb{N}^{\geq 1}, \quad \text{and} \quad \sigma_\infty^0 = 0$$

and one-cells

$$\sigma_k^1 = \left( \frac{1}{k}, \frac{1}{k+1} \right), \quad k \in \mathbb{N}^{\geq 1}.$$

At first glance, this looks like a CW decomposition; it certainly satisfies [Axiom \(CW1\)](#) and [Axiom \(CW2\)](#). However, consider the set

$$A = \{a_k \mid k \in \mathbb{N}^{\geq 1}\},$$

where

$$a_k = \frac{1}{2} \left( \frac{1}{k} + \frac{1}{k+1} \right)$$

is the midpoint of the interval  $\sigma_k^1$ . We have  $A \cap \sigma_k^0 = \emptyset$  for all  $k$ , and  $A \cap \sigma_k^1 = \{a_k\}$  for all  $k$ . In each case,  $A \cap \bar{\sigma}_j^i$  is closed in  $\sigma_j^i$ . However, the set  $A$  is not closed in  $I$ , since it does not contain its limit point  $\lim_{n \rightarrow \infty} a_n = 0$ .

**Definition 59** (skeleton, dimension). Let  $X$  be a CW complex, and let

$$X^n = \bigcup_{\substack{\sigma \in X \\ \dim(\sigma) \leq n}} \sigma.$$

We call  $X^n$  the  $n$ -skeleton of  $X$ . If  $X$  is equal to its  $n$ -skeleton but not equal to its  $(n-1)$ -skeleton, we say that  $X$  is  $n$ -dimensional.

*Note 60.* [Axiom \(CW3\)](#) implies that  $X$  carries the direct limit topology, i.e. that

$$X \cong \varinjlim X^n.$$

**Definition 61** (subcomplex, CW pair). Let  $X$  be a CW complex. A subspace  $Y \subset X$  is a subcomplex if it has a cell decomposition given by cells of  $X$  such that for each  $\sigma \subset Y$ , we also have that  $\bar{\sigma} \subset Y$ .

We call such a pair  $(X, Y)$  a CW pair.

**Fact 62.** Let  $X$  and  $Y$  be CW complexes such that  $X$  is locally compact.<sup>5</sup> Then  $X \times Y$  is a CW complex.

<sup>5</sup>I.e. if for every point  $x$  there is an open neighborhood  $U$  containing  $x$  and a compact set  $K$  containing  $U$ .

**Lemma 63.** Let  $D$  be a subset of a CW complex such that for each cell  $\sigma \subset X$ ,  $D \cap \sigma$  consists of at most one point. Then  $D$  is discrete.

**Corollary 64.** Let  $X$  be a CW complex.

1. Every compact subset  $K \subset X$  is contained in a finite union of cells.
2. The space  $X$  is compact if and only if it is a finite CW complex.
3. The space  $X$  is locally compact if and only if it is locally finite.<sup>6</sup>

*Proof.* It is clear that 1.  $\Rightarrow$  2., since  $X$  is a subset of itself. Similarly, it is clear that 2.  $\Rightarrow$  3., since  $\square$

**Corollary 65.** If  $f: K \rightarrow X$  is a continuous map from a compact space  $K$  to a CW complex  $X$ , then the image of  $K$  under  $f$  is contained in a finite skeleton. That is to say,  $f$  factors through some  $X^n$ .

$$\begin{array}{ccccccc} & & & & & & K \\ & & & & & & \downarrow f \\ X^{n-1} & \hookrightarrow & X^n & \xleftarrow{\exists \tilde{f}} & X^{n+1} & \hookrightarrow & \dots \hookrightarrow X \end{array}$$

**Proposition 66.** Let  $A$  be a subcomplex of a CW complex  $X$ . Then  $X \times \{0\} \cup A \times [0, 1]$  is a strong deformation retract of  $X \times [0, 1]$ .

**Lemma 67.** Let  $X$  be a CW complex.

- For any subcomplex  $A \subset X$ , there is an open neighborhood  $U$  of  $A$  in  $X$  together with a strong deformation retract to  $A$ . In particular, for each skeleton  $X^n$  there is an open neighborhood  $U$  in  $X$  (as well as in  $X^{n+1}$ ) of  $X^n$  such that  $X^n$  is a strong deformation retract of  $U$ .
- Every CW complex is paracompact, locally path-connected, and locally contractible.
- Every CW complex is semi-locally 1-connected, hence possesses a univesal covering space.

**Lemma 68.** Let  $X$  be a CW complex. We have the following decompositions.

1.

$$X^n \setminus X^{n-1} = \coprod_{\sigma \text{ an } n\text{-cell}} \sigma \cong \coprod_{\sigma \text{ an } n\text{-cell}} \mathring{\mathbb{D}}^n.$$

2.

$$X^n / X^{n-1} \cong \bigvee_{\sigma \text{ an } n\text{-cell}} \mathbb{S}^n$$

*Proof.*

---

<sup>6</sup>I.e. if every point has a neighborhood which is contained in only finitely many cells.

1. Since  $X^n \setminus X^{n-1}$  is simply the union of all  $n$ -cells (which must by definition be disjoint), we have the first equality. The homeomorphism is simply because each  $n$ -cell is homeomorphic to the open  $n$ -ball.
2. For every  $n$ -cell  $\sigma$ , the characteristic map  $\Phi_\sigma$  sends  $\partial\Delta^n$  to the  $(n-1)$ -skeleton.

□

## 1.10 Cellular homology

**Lemma 69.** For  $X$  a CW complex, we always have

$$H_q(X^n, X^{n-1}) \cong \tilde{H}_q(X^n/X^{n-1}) \cong \bigoplus_{\sigma \text{ an } n\text{-cell}} \tilde{H}_q(\mathbb{S}^n).$$

*Proof.* By Lemma 67,  $(X^n, X^{n-1})$  is a good pair. The first isomorphism then follows from Proposition 51, and the second from Lemma 68. □

**Lemma 70.** Consider the inclusion  $i_n: X^n \hookrightarrow X$ .

- The induced map

$$H_n(i_n): H_n(X^n) \rightarrow H_n(X)$$

is surjective.

- On the  $(n+1)$ -skeleton we get an isomorphism

$$H_n(i_{n+1}): H_n(X^{n+1}) \cong H_n(X).$$

*Proof.* Consider the pair of spaces  $(X^{n+1}, X^n)$ . The associated long exact sequence tells us that the sequence

$$H_n(X^n) \longrightarrow H_n(X^{n+1}) \longrightarrow H_n(X^{n+1}, X^n)$$

is exact. But by Lemma 69,

$$H_n(X^{n+1}, X^n) \cong \bigoplus_{\sigma \text{ an } (n+1)\text{-cell}} \tilde{H}_n(\mathbb{S}^{n+1}) \cong 0,$$

so  $H_n(i_n): X^n \hookrightarrow X^{n+1}$  is surjective.

Now let  $m > n$ . The long exact sequence on the pair  $(X^{m+1}, X^m)$  tells us that the follow-

## 1 Homology

ing sequence is exact.

$$\begin{array}{c}
 \xrightarrow{\quad \delta \quad} H_{n+1}(X^{m+1}, X^m) \\
 \curvearrowright \\
 H_n(X^m) \longrightarrow H_n(X^{m+1}) \longrightarrow H_n(X^{m+1}, X^m)
 \end{array}$$

But again by [Lemma 69](#), both  $H_{n+1}(X^{m+1}, X^m)$  and  $H_n(X^{m+1}, X^m)$  are trivial, so

$$H_n(X^m) \rightarrow H_n(X^{m+1})$$

is an isomorphism.

Now consider  $X$  expressed as a colimit of its skeleta.

$$\begin{array}{ccccccc}
 \cdots & \longrightarrow & X^n & \longrightarrow & X^{n+1} & \longrightarrow & X^{n+2} \longrightarrow \cdots \\
 & & & \searrow & \searrow & \searrow & \\
 & & & & & & X
 \end{array}$$

Taking  $n$ th singular homology, we find the following.

$$\cdots \longrightarrow H_n(X^n) \xrightarrow{\alpha_1} H_n(X^{n+1}) \xrightarrow{\alpha_2} H_n(X^{n+2}) \xrightarrow{\alpha_3} \cdots \longrightarrow H_n(X)$$

Let  $[\alpha] \in H_n(X^n)$ , with

$$\alpha = \sum_i \alpha^i \sigma_i, \quad \sigma_i: \Delta^n \rightarrow X.$$

Since the standard  $n$ -simplex  $\Delta^n$  is compact, [Corollary 65](#) implies that each  $\sigma_i$  factors through some  $X^{n_i}$ . Therefore, each  $\sigma_i$  factors through  $X^N$  with  $N = \max_i n_i$ , and we can write

$$\sigma_i = i_N \circ \tilde{\sigma}_i, \quad \tilde{\sigma}_i: \Delta^n \rightarrow X^N.$$

Now consider

$$\tilde{\alpha} = \sum_i \alpha^i \tilde{\sigma}_i \in S_n(X^N).$$

Thus,

$$[\alpha] = \left[ \sum_i \alpha^i i_n \circ \sigma \right]$$

□

**Corollary 71.** Let  $X$  and  $Y$  be CW complexes.

1. If  $X^n \cong Y^n$ , then  $H_q(X) \cong H_q(Y)$  for all  $q < n$ .
2. If  $X$  has no  $q$ -cells, then  $H_q(X) \cong 0$ .

3. In particular, for an  $n$ -dimensional CW-complex  $X$  (Definition 59),  $H_q(X) = 0$  for  $q > n$ .

*Proof.*

1. This follows immediately from Lemma 70.
- 2.

□

**Definition 72** (cellular chain complex). Let  $X$  be a CW complex. The cellular chain complex of  $X$  is defined level-wise by

$$C_n(X) = H_n(X^n, X^{n-1}),$$

with boundary operator  $d_n$  given by the following composition

$$H_n(X^n, X^{n-1}) \xrightarrow{\delta} H_{n-1}(X^{n-1}) \xrightarrow{\varrho} H_{n-1}(X^{n-1}, X^{n-2})$$

where  $\varrho$  is induced by the projection

$$S_{n-1}(X^{n-1}) \rightarrow S_{n-1}(X^{n-1}, X^{n-2}).$$

This is a bona fide differential, since

$$d^2 = \varrho \circ \delta \circ \varrho \circ \delta,$$

and  $\delta \circ \varrho$  is a composition in the long exact sequence on the pair  $(X^n, X^{n-1})$ .

**Theorem 73** (comparison of cellular and singular homology). Let  $X$  be a CW complex. Then there is an isomorphism

$$\Upsilon_n: H_n(C_\bullet(X), d) \cong H_n(X).$$

**Example 74** (complex projective space). Consider the complex projective space  $\mathbb{C}P^n$ . We know that  $\mathbb{C}P^0 = \text{pt}$ , and from the homogeneous coordinates

$$[x_0 : \cdots : x_n]$$

on  $\mathbb{C}P^n$ , we have a decomposition

$$\mathbb{C}P^n \cong \mathbb{C}^n \sqcup \mathbb{C}P^{n-2}.$$

Inductively, we find a decomposition

$$\mathbb{C}P^n \cong \mathbb{C}^n \sqcup \mathbb{C}^{n-1} \sqcup \cdots \sqcup \mathbb{C}^0,$$

## 1 Homology

giving us a cell decomposition

$$\mathbb{C}P^{2n} \cong \mathbb{R}^{2n} \sqcup \mathbb{R}^{2n-2} \sqcup \dots \sqcup \mathbb{R}^0.$$

This is a CW complex because

The cellular chain complex is as follows.

$$\begin{array}{ccccccc} 2n & & 2n-1 & & 2n-2 & & \dots & & 1 & & 0 \\ \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} & \longrightarrow & \dots & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} \end{array}$$

The differentials are all zero. Thus, we have

$$H_k(\mathbb{C}P^n) = \begin{cases} \mathbb{Z}, & k = 2i, 0 \leq i \leq n \\ 0, & \text{otherwise.} \end{cases}$$

**Example 75** (real projective space). As in the complex case, appealing to homogeneous coordinates gives a cell decomposition

$$\mathbb{R}P^n \cong \mathbb{R}^n \sqcup \mathbb{R}^{n-1} \sqcup \dots \sqcup \mathbb{R}^0.$$

The cellular chain complex is thus as follows.

$$\begin{array}{ccccccc} n & & n-1 & & n-2 & & \dots & & 1 & & 0 \\ \mathbb{Z} & \longrightarrow & \mathbb{Z} & \longrightarrow & \mathbb{Z} & \longrightarrow & \dots & \longrightarrow & \mathbb{Z} & \longrightarrow & \mathbb{Z} \end{array}$$

Unlike the complex case, we don't know how the differentials behave, so we can't calculate the homology directly.

### 1.10.1 Euler characteristic

Here's one last application of CW stuff: euler characteristic.

**Definition 76** (Euler characteristic). Let  $X$  be a finite CW complex. The Euler characteristic of  $X$  is defined to be

$$\chi(X) = \sum_{n \geq 0} (-1)^n \operatorname{rk}(H_n(X; \mathbb{Z}))$$

where for an abelian group  $A$ ,  $\operatorname{rk}(A)$  denotes the number of free summands.

Note that the above sum must be finite since there is some simplex of highest degree,

say  $k$ , so  $H_{k'}(X; \mathbb{Z}) \cong 0$  for all  $k' > k$ .

**Proposition 77.** For  $X$  a finite CW complex, denote by  $c_n(X)$  the number of  $n$ -cells. Then

$$\chi(X) = \sum_{n \geq 0} (-1)^n c_n(X).$$

*Proof.* We will use the following fact. For any short exact sequence

$$0 \longrightarrow A \hookrightarrow B \twoheadrightarrow C \longrightarrow 0 ,$$

we have the equality

$$\text{rk}(B) = \text{rk}(A) + \text{rk}(C).$$

Consider the short exact sequences

$$0 \longrightarrow Z_n \hookrightarrow C_n \twoheadrightarrow B_{n-1} \longrightarrow 0$$

and

$$0 \longrightarrow B_n \hookrightarrow Z_n \twoheadrightarrow H_n \longrightarrow 0 .$$

Applying our rank formula to both and summing leads to the equation

$$\text{rk}(C_n) = \text{rk}(B_{n-1}) + \text{rk}(B_n) + \text{rk}(H_n).$$

Substituting  $C_n(X)$  by the above and summing results in the  $B_i$  terms cancelling each other in the alternating sum, giving us the result we want.  $\square$

**Proposition 78.** For finite CW complexes  $X$  and  $Y$ , we have

$$\chi(X \times Y) \cong \chi(X) \times \chi(Y).$$

*Proof.* First, note that for  $\mathbb{S}^n$   $\square$

## 1.11 Homology with coefficients

**Definition 79** (homology with coefficients). Let  $G$  be an abelian group, and  $X$  a topological space. The singular chain complex of  $X$  with coefficients in  $G$  is the chain complex

$$S(X; G) = S(X) \otimes_{\mathbb{Z}} G.$$

The  $n$ th singular homology of  $X$  with coefficients in  $G$  is the  $n$ th homology

$$H_n(X; G) = H_n(S(X; G)).$$

## 1 Homology

We can relate homology with integral coefficients (i.e. standard homology) and homology with coefficients in  $G$ .

**Theorem 80** (topological universal coefficient theorem for homology). For every topological space  $X$  there is a short exact sequence

$$0 \longrightarrow H_n(X) \otimes G \hookrightarrow H_n(X; G) \twoheadrightarrow \text{Tor}(H_{n-1}(X), G) \longrightarrow 0 .$$

Furthermore, this sequence splits non-canonically, telling us that

$$H_n(X; G) \cong (H_n(X) \otimes G) \oplus \text{Tor}_1^{\mathbb{Z}}(H_{n-1}(X), G).$$

*Proof.* [Theorem 80](#). □

## 1.12 The topological Künneth formula

Let  $X$  and  $Y$  be topological spaces. Plugging  $C = S(X)$  and  $D = S(Y)$  into [Theorem ??](#) tells us that the following sequence is split exact.

$$0 \rightarrow \bigoplus_{p+q=n} H_p(X) \otimes H_q(Y) \hookrightarrow H_n(S(X)_\bullet \otimes S(Y)_\bullet) \twoheadrightarrow \bigoplus_{p+q=n-1} \text{Tor}_1(H_p(X), H_q(Y)) \rightarrow 0 .$$

It turns out that we can relate  $H_n(S(X)_\bullet \otimes S(Y)_\bullet)$  and  $H_n(X \times Y)$ . In fact, they turn out to be isomorphic; this is known as the *Eilenberg-Zilber theorem*.

### 1.12.1 The Eilenberg-Zilber theorem: with acyclic models

This turns out to be a direct consequence of the acyclic model theorem ([Theorem 17](#)).

**Lemma 81.** The functors

$$F = S(-) \otimes S(-): \mathbf{Top} \times \mathbf{Top} \rightarrow \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$$

and

$$G = S(- \times -): \mathbf{Top} \times \mathbf{Top} \rightarrow \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$$

are both free and acyclic ([Definition 15](#)) on

$$\mathcal{M} = \{(\Delta^p, \Delta^q)\}_{p,q=0,1,\dots}$$

*Proof.* Clear, basically. □

**Proposition 82.** There is a chain homotopy equivalence between  $F$  and  $G$  as defined in [Lemma 81](#).

*Proof.* Consider the following diagram.

$$\begin{array}{ccc}
 & f_0: x \otimes y \mapsto (x, y) & \\
 & \curvearrowright & \\
 S_0(X) \otimes S_0(Y) & & S_0(X \times Y) \\
 & \curvearrowleft & \\
 & g_0: (x, y) \mapsto x \otimes y & 
 \end{array}$$

We can find lifts...

□

### 1.12.2 The Eilenberg-Zilber theorem: without acyclic models

We first define a so-called *homology cross product*

$$\times: S_p(X) \otimes S_q(Y) \rightarrow S_{p+q}(X \times Y),$$

and then show that it descends to homology.

Our goal is to find a way of making a  $p$ -simplex in  $X$  and a  $q$ -simplex in  $Y$  into a  $(p+q)$ -simplex in  $X \times Y$ , called the *homology cross product*. At least in the case that one of  $p$  or  $q$  is equal to zero, it is clear what to do, since the Cartesian product of a  $p$ -simplex with a zero-simplex is in an obvious way a  $p$ -simplex. In more general cases, however, we have to be clever. The strategy is to write down a list of properties that we would like our homology cross product to have, and then show that there exists a unique map satisfying them.

**Lemma 83.** We can define a homomorphism

$$\times: S_p(X) \otimes S_q(Y) \rightarrow S_{p+q}(X \times Y), \quad p, q \geq 0,$$

with the following properties.

1. For all points  $x_0 \in X$  viewed as zero-chains in  $S_0(X)$  and all  $\beta: \Delta^q \rightarrow Y$ , we have

$$(x_0 \times \beta)(t_0, \dots, t_q) = (x_0, \beta(t_0, \dots, t_q));$$

conversely, for  $\alpha \in S_p(X)$  and  $y_0 \in Y$ , we have

$$(\alpha \times y_0)(t_0, \dots, t_p) = (\alpha(t_0, \dots, t_p), y_0).$$

2. The map  $\times$  is natural in the sense that the square

$$\begin{array}{ccc}
 S_p(X) \otimes S_q(Y) & \xrightarrow{\times} & S_{p+q}(X \times Y) \\
 \downarrow & & \downarrow \\
 S_p(X') \otimes S_q(Y') & \xrightarrow{\times} & S_{p+q}(X' \times Y')
 \end{array}$$

## 1 Homology

commutes.

3. The map  $\times$  satisfies the Leibniz rule in the sense that

$$\partial(\alpha \times \beta) = \partial(\alpha) \times \beta + (-1)^p \alpha \times \partial(\beta).$$

*Proof.* As a warm up, let us work out some hypothetical consequences of our formulae, in the special case that  $X = \Delta^p$  and  $Y = \Delta^q$ . In this case, we have

$$\text{id}_{\Delta^p} \in S_p(\Delta^p), \quad \text{id}_{\Delta^q} \in S_q(\Delta^q),$$

so we can take the homology cross product  $\text{id}_{\Delta^p} \times \text{id}_{\Delta^q} \in S_{p+q}(\Delta^p \times \Delta^q)$ . By the Leibniz rule, we have

$$\partial(\text{id}_{\Delta^p} \times \text{id}_{\Delta^q}) = \partial(\text{id}_{\Delta^p}) \times \text{id}_{\Delta^q} + (-1)^p \text{id}_{\Delta^p} \times \partial(\text{id}_{\Delta^q}).$$

This is now a perfectly well-defined element of  $S_{p+q-1}(\Delta^p \times \Delta^q)$ , which we will give the nickname  $R$ .<sup>7</sup>

A trivial computation shows that  $\partial R = 0$ , so there exists a  $c \in S_{p+q}(\Delta^p \times \Delta^q)$  with  $\partial c = R$ . We choose some such  $c$  and define  $\text{id}_{\Delta^p} \times \text{id}_{\Delta^q} = c$ .

We now use the trick of expressing some  $\alpha: \Delta^p \rightarrow X$  as  $S_p(\alpha)(\text{id}_{\Delta^p})$ . Then

$$\alpha \times \beta = S_p(\alpha)(\text{id}_{\Delta^p}) \times S_q(\beta)(\text{id}_{\Delta^q}).$$

But then the naturality forces our hand; chasing  $\text{id}_{\Delta^p} \otimes \text{id}_{\Delta^q}$  around the naturality square

$$\begin{array}{ccc} S_p(\Delta^p) \otimes S_q(\Delta^q) & \xrightarrow{\times} & S_{p+q}(\Delta^p \times \Delta^q) \\ S_p(\alpha) \otimes S_q(\beta) \downarrow & & \downarrow S_{p+q}(\alpha, \beta) \\ S_p(X) \otimes S_q(Y) & \xrightarrow{\times} & S_{p+q}(X \times Y) \end{array}$$

tells us that

$$\begin{aligned} S_{p+q}(\alpha, \beta)(\text{id}_{\Delta^p} \times \text{id}_{\Delta^q}) &= S_p(\alpha)(\text{id}_{\Delta^p}) \times S_q(\beta)(\text{id}_{\Delta^q}) \\ S_{p+q}(\alpha, \beta)(c) &= \alpha \times \beta. \end{aligned}$$

Thus, we can define

$$\alpha \times \beta = S_{p+q}(\alpha, \beta)(c).$$

This satisfies all the desired properties by construction. □

**Proposition 84.** Any natural transformations  $f, g$  with components

$$f_{X,Y}, g_{X,Y}: (S(X) \otimes S(Y))_{\bullet} \rightarrow S_{\bullet}(X \times Y)$$

---

<sup>7</sup>I think there's an induction argument hidden here.

which agree in degree zero and send  $x_0 \otimes y_0 \mapsto (x_0, y_0)$  are chain homotopic.

*Proof.* First, suppose that  $X = \Delta^p$  and  $Y = \Delta^q$ . Then  $(S(\Delta^p) \otimes S(\Delta^q))_\bullet$  is free, hence certainly projective, and  $S(\Delta^p \times \Delta^q)$  is acyclic, so the result follows from Lemma ??: that is, we get a chain homotopy  $H$  with components

$$H_n: (S_\bullet(\Delta^p) \otimes S_\bullet(\Delta^q))_n \rightarrow S_{n+1}(\Delta^p \times \Delta^q)$$

such that

$$\partial H_n + H_{n-1} \partial = f_n - g_n.$$

□

### 1.12.3 The topological Künneth formula

**Theorem 85** (topological Künneth formula). For any topological spaces  $X$  and  $Y$ , we have the following short exact sequence, natural in  $X$  and  $Y$ .

$$0 \rightarrow \bigoplus_{p+q=n} H_p(X) \otimes H_q(X) \hookrightarrow H_n(X \times Y) \twoheadrightarrow \bigoplus_{p+q=n-1} \text{Tor}(H_p(X), H_q(Y)) \rightarrow 0$$

This sequence splits, but not canonically, and the splitting is not natural.

**Example 86.** Consider the torus  $T^2 \cong \mathbb{S}^1 \times \mathbb{S}^1$ . We have that the following sequence is exact.

$$0 \rightarrow \bigoplus_{p+q=n} H_p(\mathbb{S}^1) \otimes H_q(\mathbb{S}^1) \rightarrow H_n(\mathbb{S}^1 \times \mathbb{S}^1) \rightarrow \bigoplus_{p+q=n-1} \text{Tor}(H_p(\mathbb{S}^1), H_q(\mathbb{S}^1)) \rightarrow 0$$

Because  $H_i(\mathbb{S})$  is either 0 or  $\mathbb{Z}$ , hence certainly projective, we get that

$$H_n(\mathbb{S}^1 \times \mathbb{S}^1) \cong \bigoplus_{p+q=n} H_p(\mathbb{S}) \otimes H_q(\mathbb{S}) \cong \begin{cases} \mathbb{Z} & n = 0 \\ \mathbb{Z}^2 & n = 1 \\ \mathbb{Z} & n = 2 \\ 0 & \text{otherwise.} \end{cases}$$

By induction,  $H_n(\mathbb{S}^k) = \mathbb{Z}^{\binom{k}{n}}$ .

**Example 87.** For a space of the form  $X \times \mathbb{S}^n$ , we get

$$H_n(X \times \mathbb{S}^n) \cong H_q(X) \oplus H_{q-n}(X).$$

## 1.13 The Eilenberg-Steenrod axioms

Denote by  $T$  the functor

$$T: \mathbf{Pair} \rightarrow \mathbf{Pair}; \quad (X, A) \mapsto (A, \emptyset); \quad (f: (X, A) \rightarrow (Y, B)) \mapsto f|_A.$$

**Definition 88** (homology theory). Let  $A$  be an abelian group. A homology theory with coefficients in  $A$  is a sequence of functors

$$H_n: \mathbf{Pair} \rightarrow \mathbf{Ab}, \quad n \geq 0$$

together with natural transformations

$$\delta: H_n \Rightarrow H_{n-1} \circ T$$

satisfying the following conditions.

1. **Homotopy:** Homotopic maps induce the same maps on homology; that is,

$$f \sim g \implies H_n(f) = H_n(g) \quad \text{for all } f, g, n.$$

2. **Excision:** If  $(X, A)$  is a pair with  $U \subset X$  such that  $\bar{U} \subset \mathring{A}$ , then the inclusion  $i: (X \setminus U, A \setminus U) \hookrightarrow (X, A)$  induces an isomorphism

$$H_n(i): H_n(X \setminus U, A \setminus U) \cong H_n(X, A)$$

for all  $n$ .

3. **Dimension:** We have

$$H_n(\text{pt}) = \begin{cases} A, & n = 0 \\ 0, & \text{otherwise.} \end{cases}$$

4. **Additivity:** If  $X = \coprod_{\alpha} X_{\alpha}$  is a disjoint union of topological spaces, then

$$H_n(X) = \bigoplus_{\alpha} H_n(X_{\alpha}).$$

5. **Exactness:** Each pair  $(X, A)$  induces a long exact sequence on homology.

We have seen that singular homology satisfies all of these axioms, and hence is a homology theory.
