# 1 Introduction

## **Homework:**

- Must submit more than 50% correct solutions in order to take the final exam (oral).
- Posted on Monday after the lecture
- Submitted on following Monday in lecture
- Discuss following Tuesday, 16:45, room 430

## 2 Chain complexes

Homological algebra is about chain complexes.

**Definition 1** (chain complex). Let  $R$  be a ring.<sup>1</sup> A chain complex of  $R$ -modules, denoted  $(C_\bullet, d)$ , consists of the following data:

- For each  $n \in \mathbb{Z}$ , an  $R$ -module  $C_n$ , and
- $R$ -linear maps  $d_n: C_n \rightarrow C_{n-1}$ , called the *differentials*,

such that the differentials satisfy the relation

$$d_{n-1} \circ d_n = 0.$$

**Example 2** (Syzygies). Let  $R = \mathbb{C}[x_1, \dots, x_k]$ . Following Hilbert, we consider a finitely generated<sup>2</sup>  $R$ -module  $M$ . The ring  $R$  is Noetherian, so by Hilbert's basis theorem,  $M$  is Noetherian, hence has finitely many generators  $a_1, \dots, a_k$ .

Denote by  $R^k$  the free  $R$ -module with  $k$  generators, and consider

$$\phi: R^k \rightarrow M; \quad e_i \mapsto a_i.$$

This map is surjective, but it may have a kernel, called the *module of first Syzygies*, denoted  $\text{Syz}^1(M)$ . This kernel consists of those  $x$  such that

$$x = \sum_{i=1}^k \lambda_i e_i \xrightarrow{\phi} \sum_{i=1}^k \lambda_i a_i = 0.$$

This kernel is again a module, the module of relations.

By Hilbert's basis theorem (since polynomial rings over a field are Noetherian),  $\text{Syz}^1(M)$  is again a finitely generated  $R$ -module. Hence, pick finite set of generators  $b_i$ ,  $1 \leq i \leq \ell$ , and look at

$$R^\ell \rightarrow \text{Syz}^1(M); \quad e_i \mapsto b_i.$$

In general, there is non-trivial kernel, denoted  $\text{Syz}^2(M)$ . This consists of relation between relations.

We can keep going. This gives us a sequence  $\text{Syz}^\bullet(M)$  corresponding to relations be-

<sup>1</sup>Associative, with unit. Not necessarily commutative.

<sup>2</sup>i.e. expressible as an  $R$ -linear combination of finitely many generators.

## 2 Chain complexes

tween relations between...between relations.

From this we build a chain complex  $(C_\bullet, d)$ , where  $C_n$  corresponds to the  $n$ th copy of  $R^k$ , known as the *free resolution* of  $M$ .

*Hilbert's Syzygy theorem* tells us that every finitely generated  $\mathbb{C}[x_1, \dots, x_n]$ -module admits a free resolution of length at most  $n$ .

**Example 3** (simplicial complexes). Let  $N \geq 0$ . A collection  $K \subset \mathcal{P}(\{0, \dots, n\})$  of subsets is called a *simplicial complex* if it is closed under the taking of subsets in the sense that if for all  $\sigma \in K$ ,

$$\tau \subset \sigma \implies \tau \in K.$$

For every  $n \geq 0$ , we define the  $n$ -*simplices* of  $K$  to be the set

$$K_n = \{\sigma \in K \mid |\sigma| = n + 1\}.$$

Every  $\sigma \in K_n$  can be expressed uniquely as  $\sigma = \{x_0, \dots, x_n\}$ , with  $x_0 < \dots < x_n$ . Define the  $i$ th *face* of  $\sigma$  to be

$$\partial_i \sigma = \{x_0, \dots, x_{i-1}, x_{i+1}, \dots, x_n\}.$$

Let  $R$  be a ring. Define

$$C_n(K, R) = \bigoplus_{\sigma \in K_n} R_{e_\sigma},$$

where the subscripts are simply labels. Further, define

$$d: C_n(K, R) \rightarrow C_{n-1}(K, R); \quad e_\sigma \mapsto \sum_{i=0}^n (-1)^i e_{\partial_i \sigma}.$$

This is a complex because...

**Example 4.** Let  $k$  be a field, and  $A$  an associative  $k$ -algebra. We define a complex of vector spaces

$$\dots \xrightarrow{d} A^{\otimes n} \xrightarrow{d} \dots \xrightarrow{d} A^{\otimes 3} \xrightarrow{d} A \otimes A \xrightarrow{d} A,$$

where  $d$  is defined by the formula

$$d(a_0 \otimes \cdots \otimes a_n) = \sum_{i=0}^{n-1} (-1)^i a_0 \otimes \cdots \otimes a_i a_{i+1} \otimes \cdots \otimes a_n + (-1)^n a_n a_0 \otimes \cdots \otimes a_{n-1}.$$

This complex is known as the *cyclic bar complex*.

**Definition 5** (cycle, boundary, homology). Let  $(C_\bullet, d)$  be a chain complex. We make the following definitions.

- The space  $\ker d_m$  is known as the space of  $n$ -cycles, and denoted  $Z_n(C_\bullet)$ .
- The space  $\operatorname{im} d_{m+1}$  is known as the space of  $n$ -boundaries, and denoted  $B_n(C_\bullet)$ .
- The space

$$\frac{Z_n}{B_n} = H_n(C_\bullet)$$

is known as the  $n$ th homology of  $C$ .

**Definition 6** (exact). We say that a chain complex  $(C_\bullet, d)$  is exact at  $n \in \mathbb{Z}$  if  $H_n(C_\bullet) = 0$ .

**Definition 7** (exact sequence). We say that a sequence

$$C_k \xrightarrow{d} C_{k-1} \xrightarrow{d} \cdots \xrightarrow{d} C_\ell$$

with  $d^2 = 0$  is exact if it is exact at  $k-1, k-2, \dots, \ell+1$ .

**Definition 8** (short exact sequence). A short exact sequence is an exact sequence of the form

$$0 \longrightarrow A \xrightarrow{f} B \xrightarrow{g} C \longrightarrow 0.$$

Equivalently, such a sequence is exact if

- $f$  is a monomorphism
- $g$  is an epimorphism
- $H_B = 0$ .

**Example 9.**

- The sequence

$$0 \longrightarrow \mathbb{Z} \xrightarrow{\times 2} \mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \longrightarrow 0$$

is exact.

- The sequence

$$0 \longrightarrow \mathbb{Z}/4\mathbb{Z} \xrightarrow{\times 2} \mathbb{Z}/4\mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \longrightarrow 0$$

## 2 Chain complexes

is not exact since the map  $x \mapsto 2x$  is not injective.

- The sequence

$$\mathbb{Z}/4\mathbb{Z} \xrightarrow{\times 2} \mathbb{Z}/4\mathbb{Z} \xrightarrow{\pi} \mathbb{Z}/2\mathbb{Z} \longrightarrow 0$$

is exact.

## 3 Basic algebra

Strictly speaking, this chapter shouldn't need to exist, but my algebra knowledge is pretty hopeless so I'll be putting stuff I should know already here.

### 3.1 Exactness

**Proposition 10.** Let  $R$  be a ring, and  $M$  a left  $R$ -module. Then both the hom functors

$$\text{Hom}(M, -), \quad \text{Hom}(-, M)$$

are left exact.

*Proof.* Let

$$0 \longrightarrow A \xrightarrow{f} B \xrightarrow{g} C \longrightarrow 0$$

be an exact sequence. First, we show that  $\text{Hom}(M, A)$  is exact, i.e. that

$$0 \longrightarrow \text{Hom}(M, A) \xrightarrow{f_*} \text{Hom}(M, B) \xrightarrow{g_*} \text{Hom}(M, C)$$

is an exact sequence of abelian groups.

First, we show that  $f_*$  is injective. To see this, let  $\alpha: M \rightarrow A$  such that  $f_*(\alpha) = 0$ . By definition,  $f_*(\alpha) = f \circ \alpha$ , and

$$f \circ \alpha = 0 \implies \alpha = 0$$

because  $f$  is a monomorphism.

Similarly,  $\text{im } f \subseteq \ker g$  because

$$(g_* \circ f_*)(\beta) = g \circ f \circ \beta = 0.$$

### 3 Basic algebra

It remains only to check that  $\ker g \subseteq \operatorname{im} f$ . To this end, let  $\gamma: M \rightarrow B$  such that  $g_*\gamma = 0$ .

$$\begin{array}{ccccccc}
 & & & M & & & \\
 & & \swarrow \exists! \delta & \downarrow \gamma & \searrow 0 & & \\
 0 & \longrightarrow & A & \xrightarrow{f} & B & \xrightarrow{g} & C \longrightarrow 0
 \end{array}$$

Then  $\operatorname{im} \gamma \subset \ker g = \operatorname{im} f$ , so  $\gamma$  factors through  $A$ ; that is to say, there exists a  $\delta: M \rightarrow A$  such that  $f_*\delta = \gamma$ .  $\square$

This theorem is a shadow of a much, much stronger result: Exactness of functor  $F: \mathcal{A} \rightarrow \mathcal{B}$  between abelian categories is a consequence of preservation of certain (co)limits. More concretely, we have the following.

## 3.2 Tensor products

**Definition 11** (tensor product). Let  $R$  be a (not necessarily commutative) ring  $M$  a right  $R$ -module, and  $N$  a left  $R$ -module. The tensor product  $M \otimes_R N$  satisfies the following universal property...

Even for modules over non-commutative rings, we have the following version of tensor-hom adjunction.

**Proposition 12.** Let  $R$  be a ring,  $M$  a right  $R$ -module, and  $N$  a left  $R$ -module. There is an adjunction

$$- \otimes_R N : \mathbf{Mod}\text{-}R \longleftrightarrow \mathbf{Ab} : \operatorname{Hom}_{\mathbf{Ab}}(N, -).$$

*Proof.* We show that there is a natural bijection

$$\operatorname{Hom}_{\mathbf{Ab}}(M \otimes_R N, P) \simeq \operatorname{Hom}_{\mathbf{Ab}}(M, \operatorname{Hom}_{\mathbf{Mod}\text{-}R}(N, P)).$$

$\square$

## 3.3 Projective and injective modules

**Definition 13** (projective, injective module). Let  $R$  be a ring. An  $R$ -module  $M$  is said to be projective if the functor  $\operatorname{Hom}(P, -)$  is exact, and injective if the functor  $\operatorname{Hom}(-, P)$  is exact.

We know (from [Proposition 10](#)) that the hom functor is left exact in both slots. Therefore, we have the following immediate classification of projective objects.

**Proposition 14.** An  $R$ -module  $P$  is projective if and only if for every epimorphism  $g: B \twoheadrightarrow C$  and every morphism  $p: P \rightarrow C$ , there exists a morphism  $\tilde{p}: P \rightarrow B$  such that the following diagram commutes.

$$\begin{array}{ccc} & P & \\ \swarrow \exists \tilde{p} & \downarrow p & \\ B & \xrightarrow{g} & C \end{array}$$

Similarly, a module  $Q$  is injective if for every monomorphism  $A \hookrightarrow B$  and map  $g: A \rightarrow Q$ , there exists a homomorphism  $\tilde{g}$  such that the following diagram commutes.

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ \downarrow p & \swarrow \exists \tilde{p} & \\ Q & & \end{array}$$

*Proof.* In the projective case, this condition precisely encodes the condition that  $f_*$  is an epimorphism; in the injective case,  $\square$

**Proposition 15.** Let  $R$  be a ring. A module  $P$  is projective if and only if it is a direct summand of a free module, i.e. if there exists an  $R$ -module  $M$  and a free  $R$ -module  $F$  such that

$$F \simeq P \oplus M.$$

*Proof.* First, suppose that  $P$  is projective. We can always express  $P$  in terms of a set of generators and relations. Denote by  $F$  the free  $R$ -module over the generators, and consider the following short exact sequence.

$$0 \longrightarrow \ker \pi \hookrightarrow F \xrightarrow{\pi} P \longrightarrow 0$$

An easy consequence of the splitting lemma is that any short exact sequence with a projective in the final spot splits, so

$$F \simeq P \oplus \ker \pi$$

as required.

Conversely, suppose that  $P \oplus M \simeq F$ , for  $F$  free, and  $P$  and  $M$  arbitrary. Certainly, the following lifting problem has a solution (by lifting generators).

$$\begin{array}{ccc} & P \oplus M & \\ \swarrow \exists (j,k) & \downarrow (f,g) & \\ N & \xrightarrow{\quad} & M \end{array}$$

### 3 Basic algebra

In particular, this gives us the following solution to our lifting problem,

$$\begin{array}{ccc}
 & P & \\
 \swarrow \exists j & \downarrow f & \\
 N & \twoheadrightarrow & M
 \end{array}$$

exhibiting  $P$  as projective.

□

# 4 Abelian categories

## 4.1 Basics

In this chapter we recall some basic results.

A category is *Ab-enriched* if it is enriched over the symmetric monoidal category  $(\mathbf{Ab}, \otimes_{\mathbb{Z}})$ . In an  $\mathbf{Ab}$ -enriched category with finite products, products agree with coproducts, and we call both direct sums. We call an  $\mathbf{Ab}$ -enriched category with finite direct sums an *additive* category, and we call a functor between additive categories such that the maps

$$\mathrm{Hom}(A, B) \rightarrow \mathrm{Hom}(F(A), F(B))$$

are homomorphisms of abelian groups an *additive functor*. A *pre-abelian* category is an additive category such that every morphism has a kernel and a cokernel, and an *abelian category* is a pre-abelian category such that every monic is the kernel of its cokernel, and every epic is the cokernel of its kernel.

This immediately implies the following results.

- Kernels are monic and cokernels are epic
- Since the equalizer of  $f$  and  $g$  is the kernel of  $f - g$ , abelian categories have all finite limits, and dually colimits.

As the following proposition shows, additive functors from additive categories preserve direct sums.

**Lemma 16.** Let  $A$  and  $B$  be objects in an additive category  $\mathcal{A}$ , and let  $X$  be an object in  $\mathcal{A}$  equipped with morphisms as follows,

$$\begin{array}{ccc} A & & A \\ & \searrow i_A & \nearrow \pi_A \\ & X & \\ & \nearrow i_B & \searrow \pi_B \\ B & & B \end{array}$$

such that the following equations hold.

$$\begin{aligned} i_A \circ \pi_A + i_B \circ \pi_B &= \text{id}_X \\ \pi_A \circ i_B &= 0 = \pi_B \circ i_A \\ \pi_A \circ i_A &= \text{id}_A \\ \pi_B \circ i_B &= \text{id}_B \end{aligned}$$

Then the  $\pi$ s and  $i$ s exhibit  $X \simeq A \oplus B$ .

**Corollary 17.** Let  $F: \mathcal{A} \rightarrow \mathcal{B}$  be an additive functor between additive categories. Then  $F$  preserves direct sums in the sense that there is a natural isomorphism

$$F(a \oplus b) \simeq F(a) \oplus F(b).$$

Once it is known that a category  $\mathcal{A}$  is abelian, a number of other categories are immediately known to be abelian.

- The category  $\mathbf{Ch}(\mathcal{A})$  of chain complexes in  $\mathcal{A}$  is abelian, as we will see in
- For any small category  $I$ , the category  $\mathbf{Fun}(I, \mathcal{A})$  of  $I$ -diagrams in  $\mathcal{A}$  is abelian.

## 4.2 Embedding theorems

In ordinary category theory, when manipulating a locally small category it is often helpful to pass through the Yoneda embedding, which gives a (fully) faithful rendition of the category under consideration in the category  $\mathbf{Set}$ . One of the reasons that this is so useful is that the category  $\mathbf{Set}$  has a lot of structure which can use to prove things about the subcategory of  $\mathbf{Set}$  in which one lands. Having done this, one can then use the fully faithfulness to translate results to the category under consideration.

This sort of procedure, namely embedding a category which is difficult to work with into one with more desirable properties and then translating results back and forth, is very powerful. In the context of (small) Abelian categories one has essentially the best possible such embedding, known as the Freyd-Mitchell embedding theorem, which we will revisit at the end of this section. However, for now we will content ourselves with a simpler categorical embedding, one which we can work with easily.

In abelian categories, one can define kernels and cokernels slickly, as for example the equalizer along the zero morphism. However, in full generality, we can define both kernels and cokernels in any category with a zero object:  $f$  is a kernel for  $g$  if and only if the diagram below is a pullback, and a  $g$  is a cokernel of  $f$  if and only if the diagram

below is a pullback.

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ \downarrow & & \downarrow g \\ 0 & \longrightarrow & C \end{array}$$

This means that kernels and cokernels are very general, as categories with zero objects are a dime a dozen. For example, the category  $\mathbf{Set}_*$  of pointed sets has the singleton  $\{*\}$  as a zero object. This means that one can speak of the kernel or the cokernel of a map between pointed sets, and talk about an exact sequence of such maps.

Given an abelian category  $\mathcal{A}$ , suppose one could find an embedding  $\mathcal{H}: \mathcal{A} \rightarrow \mathbf{Set}_*$  which reflected exactness in the sense that if one started with a sequence  $A \rightarrow B \rightarrow C$  in  $\mathcal{A}$ , mapped it into  $\mathbf{Set}_*$  finding a sequence  $\mathcal{H}(A) \rightarrow \mathcal{H}(B) \rightarrow \mathcal{H}(C)$ , and found that this sequence was exact, one could be sure that  $A \rightarrow B \rightarrow C$  had been exact to begin with. Then every time one wanted to check the exactness of a sequence, one could embed that sequence in  $\mathbf{Set}_*$  using  $\mathcal{H}$  and check exactness there. Effectively, one could check exactness of a sequence in  $\mathcal{A}$  by manipulating the objects making up the sequence as if they had elements.

Or, suppose one could find an embedding as above as above which sent only zero morphisms to zero morphisms. Then one could check that a diagram commutes (equivalently, that the difference between any two different ways of getting between objects is equal to 0) by checking the that the image of the diagram under our functor  $\mathcal{H}$  commutes.

In fact, for  $\mathcal{A}$  small, we will find a functor which satisfies both of these and more. Then, just as we are feeling pretty good about ourselves, we will state the Freyd-Mitchell embedding theorem, which blows our pitiful result out of the water.

We now construct our functor to  $\mathbf{Set}_*$ .

**Definition 18** (category of contravariant epimorphisms). Let  $\mathcal{A}$  be a small abelian category. Define a category  $\mathcal{A}_\leftarrow$  with  $\text{Obj}(\mathcal{A}_\leftarrow) = \text{Obj}(\mathcal{A})$ , and whose morphisms are defined by

$$\text{Hom}_{\mathcal{A}_\leftarrow}(X, Y) = \{f: Y \rightarrow X \text{ in } \mathcal{A} \mid f \text{ epimorphism}\}.$$

Note that this is indeed a category since the identity functor is an epimorphism and epimorphisms are closed under composition.

Now for each  $A \in \mathcal{A}$ , we define a functor

$$\mathcal{H}_A: \mathcal{A}_\leftarrow \rightarrow \mathbf{Set}_*; \quad Z \mapsto \text{Hom}_{\mathcal{A}}(Z, A)$$

and sends a morphism  $f: Z_1 \rightarrow Z_2$  in  $\mathcal{A}_\leftarrow$  (which is to say, an epimorphism  $\tilde{f}: Z_2 \twoheadrightarrow Z_1$  in  $\mathcal{A}$ ) to the map

$$\mathcal{H}_A(f): \text{Hom}_{\mathcal{A}}(Z_1, A) \rightarrow \text{Hom}_{\mathcal{A}}(Z_2, A); \quad (\alpha: Z_1 \rightarrow A) \mapsto (\alpha \circ \tilde{f}: Z_2 \rightarrow A).$$

#### 4 Abelian categories

Note that the distinguished point in the hom sets above is given by the zero morphism.

**Definition 19** (member functor). Let  $\mathcal{A}$  be a small abelian category. We define a functor  $\mathcal{M}: \mathcal{A} \rightarrow \mathbf{Set}_*$  on objects by

$$A \mapsto \mathcal{M}(A) = \operatorname{colim} \mathcal{H}_A.$$

On morphisms, functoriality comes from the functoriality of the colimit and the co-Yoneda embedding.

Strictly speaking, we have finished our construction, but it doesn't do us much good as stated. It turns out that the sets  $\mathcal{M}(\mathcal{A})$  have a much simpler interpretation.

**Proposition 20.** for any  $A \in \mathcal{A}$ , the value of the member functor  $\mathcal{M}(A)$  is

$$\mathcal{M}(A) = \bigsqcup_{X \in \mathcal{A}} \operatorname{Hom}(X, A) / \sim,$$

where  $g \sim g'$  if there exist epimorphisms  $f$  and  $f'$  making the below diagram commute.

$$\begin{array}{ccc} Z & \xrightarrow{f} & X \\ f' \downarrow & & \downarrow g \\ X' & \xrightarrow{g'} & A \end{array}$$

*Proof.* The colimit can be computed using the following coequalizer.

$$\bigsqcup_{\substack{f \in \operatorname{Morph}(\mathcal{A}_{\leftarrow}) \\ \tilde{f}: Y \rightarrow X}} \operatorname{Hom}_{\mathcal{A}}(X, A) \xrightleftharpoons[-\circ \tilde{f}]{\operatorname{id}} \bigsqcup_{Z \in \operatorname{Obj}(\mathcal{A}_{\leftarrow})} \operatorname{Hom}(Z, A) \xrightarrow{\operatorname{coeq}} \mathcal{M}(A)$$

On elements, we have the following.

$$\begin{array}{ccc} & \xrightarrow{\operatorname{id}} & (g: X \rightarrow A) \\ (g: X \rightarrow A) & \searrow -\circ \tilde{f} & \parallel \\ & \xrightarrow{-\circ \tilde{f}} & (g \circ \tilde{f}: Y \rightarrow A) \end{array}$$

Thus,

$$\mathcal{M}(A) = \bigsqcup_{Z \in \operatorname{Obj}(\mathcal{A}_{\leftarrow})} \operatorname{Hom}(Z, A) / \sim,$$

where  $\sim$  is the equivalence relation generated by the relation

$$(g: X \rightarrow A) R (g': X' \rightarrow A) \iff \exists f: X' \twoheadrightarrow X \text{ such that } g' = g \circ \tilde{f}.$$

The above relation is reflexive and transitive, but not symmetric. The smallest equivalence relation containing it is the following.

$$(g: X \rightarrow A) \sim (g': X' \rightarrow A) \iff \exists f: Z \twoheadrightarrow X, f': Z \twoheadrightarrow X' \text{ such that } g' \circ f' = g \circ f.$$

That is,  $g \sim g'$  if there exist epimorphisms making the below diagram commute.

$$\begin{array}{ccc} Z & \xrightarrow{f} & X \\ f' \downarrow & & \downarrow g \\ X' & \xrightarrow{g'} & A \end{array}$$

□

In summary, the elements of  $\mathcal{M}(A)$  are equivalence classes of morphisms into  $A$  modulo the above relation, and for a morphism  $f: A \rightarrow B$  in  $\mathcal{A}$ ,  $\mathcal{M}(f)$  acts on an equivalence class  $[g]$  by

$$\mathcal{M}(f): [g] \mapsto [g \circ f].$$

**Lemma 21.** Let  $f: A \rightarrow B$  be a morphism in a small abelian category  $\mathcal{A}$  such that  $f \sim 0$ . Then  $f = 0$ .

*Proof.* We have that  $f \sim 0$  if and only if there exists an object  $Z$  and epimorphisms making the following diagram commute.

$$\begin{array}{ccc} Z & \xrightarrow{g} & A \\ \downarrow & & \downarrow f \\ 0 & \longrightarrow & B \end{array}$$

But by the universal property for epimorphisms,  $f \circ g = 0$  implies  $f = 0$ . □

Now we introduce some load-lightening notation: we write  $\hat{(-)} = \mathcal{M}(-)$ .

**Lemma 22.** Let  $f: A \rightarrow B$  be a morphism in a small abelian category  $\mathcal{A}$ . Then  $f = 0$  if and only if  $\hat{f}: \hat{A} \rightarrow \hat{B} = 0$ .

*Proof.* Suppose that  $f = 0$ . Then for any  $[g] \in \hat{A}$

$$\hat{f}([g]) = [g \circ 0] = [0].$$

Thus,  $\hat{f}([g]) = [0]$  for all  $g$ , so  $\hat{f} = 0$ .

Conversely, suppose that  $\hat{f} = 0$ . Then in particular  $\hat{f}([\text{id}_A]) = [0]$ . But

$$\hat{f}([\text{id}_A]) = [\text{id}_A \circ f] = [f].$$

By Lemma 21,  $[f] = [0]$  implies  $f = 0$ .  $\square$

**Corollary 23.** A diagram commutes in  $\mathcal{A}$  if and only if its image in  $\mathbf{Set}_*$  under  $\mathcal{M}$  commutes.

*Proof.* A diagram commutes in  $\mathcal{A}$  if and only if any two ways of going from one object to another agree, i.e. if the difference of any two

I actually don't see this right now.  $\square$

**Lemma 24.** Let  $f: A \rightarrow B$  be a morphism in a small abelian category.

- The morphism  $f$  is a monomorphism if and only if  $\mathcal{M}(f)$  is an

### 4.3 Chain complexes

**Definition 25** (category of chain complexes). Let  $\mathcal{A}$  be an abelian category. A chain complex in  $\mathcal{A}$  is... The category of chain complexes in  $\mathcal{A}$ , denoted  $\mathbf{Ch}(\mathcal{A})$ , is the category whose objects are chain complexes and whose morphisms are morphisms of chain complexes, i.e....

We also define  $\mathbf{Ch}^+(\mathcal{A})$  to be the category of bounded-below chain complexes,  $\mathbf{Ch}^-(\mathcal{A})$  to be the category of bounded-above chain complexes, and  $\mathbf{Ch}^{\geq 0}(\mathcal{A})$  and  $\mathbf{Ch}^{\leq 0}(\mathcal{A})$  similarly.

**Proposition 26.** The category  $\mathbf{Ch}(\mathcal{A})$  is abelian.

*Proof.* We check each of the conditions.

The zero object is the zero chain complex, the **Ab**-enrichment is given level-wise, and the product is given level-wise as the direct sum. That this satisfies the universal property follows almost immediately from the universal property in  $\mathcal{A}$ : given a diagram of the form

$$\begin{array}{ccccc} & & Q_{\bullet} & & \\ & \swarrow f_{\bullet} & \downarrow \exists! \phi_{\bullet} & \searrow g_{\bullet} & \\ C_{\bullet} & \xleftarrow{p_1} & C_{\bullet} \times D_{\bullet} & \xrightarrow{p_2} & D_{\bullet} \end{array}$$

the only thing we need to check is that the map  $\phi$  produced level-wise is really a chain map, i.e. that

$$\phi_{n-1} \circ d_n^Q = d_n^C \oplus d_n^D \circ \phi_n.$$

By the above work, the RHS can be re-written as

$$\begin{aligned} (d_n^C \oplus d_n^D) \circ (i_1 \circ f_{n-1} + i_2 \circ g_{n-1}) &= i_1 \circ d_n^C \circ f_{n-1} + i_2 \circ d_n^D \circ g_{n-1} \\ &= i_1 \circ f_{n-1} \circ d_n^Q + i_2 \circ g_{n-1} \circ d_n^Q \\ &= (i_1 \circ f_{n-1} + i_2 \circ g_{n-1}) \circ d_n^Q, \end{aligned}$$

which is equal to the LHS.

The kernel is also defined level-wise. The standard diagram chase shows that the induced morphisms between kernels make this into a chain complex; to see that it satisfies the universal property, we need only show that the map  $\phi$  below is a chain map.

$$\begin{array}{ccccc} & & Q_\bullet & & \\ & \swarrow \phi_\bullet & \downarrow g_\bullet & \searrow 0 & \\ \ker(f_\bullet) & \xrightarrow{\iota_\bullet} & A_\bullet & \xrightarrow{f_\bullet} & B_\bullet \end{array}$$

That is, we must have

$$\phi_{n-1} \circ d_n^Q = d_n^{\ker f} \circ \phi_n. \quad (4.1)$$

The composition

$$Q_n \xrightarrow{g_n} A_n \xrightarrow{f} B_n \xrightarrow{d_n^B} B_{n-1}$$

gives zero by assumption, giving us by the universal property for kernels a unique map

$$\psi: Q_n \rightarrow \ker f_{n-1}$$

such that

$$\iota_{n-1} \circ \psi = d_n^A \circ g_n.$$

We will be done if we can show that both sides of Equation 4.1 can play the role of  $\psi$ . Plugging in the LHS, we have

$$\begin{aligned} \iota_{n-1} \circ \phi_{n-1} \circ d_n^Q &= g_{n-1} \circ d_n^Q \\ &= d_n^A \circ g_n \end{aligned}$$

as we wanted. Plugging in the RHS we have

$$\iota_{n-1} \circ d_n^{\ker f} \circ \phi_n = d_n^A \circ g_n.$$

The case of cokernels is dual.

Since a chain map is a monomorphism (resp. epimorphism) if and only if it is a monomorphism (resp. epimorphism), we have immediately that monomorphisms are the kernels of their cokernels, and epimorphisms are the cokernels of their kernels.  $\square$

The categories  $\mathbf{Ch}^+(\mathcal{A})$ , etc., are also abelian.

**Definition 27** (exact sequence). Given a morphism  $f: A \rightarrow B$ , the image  $\operatorname{im} f = \ker \operatorname{coker} f$  and the coimage is  $\operatorname{coker} \ker f$ . From this data, we build the following com-

#### 4 Abelian categories

muting diagram.

$$\begin{array}{ccccc}
 & \text{im } f & & & \\
 & \downarrow i & \searrow 0 & & \\
 A & \xrightarrow{f} & B & \xrightarrow{g} & C \\
 & \downarrow p & \nearrow & & \\
 & \text{coker } f & & & 
 \end{array}$$

Since  $g \circ i = 0$ ,  $i$  factors through  $\ker g$ , giving us a morphism  $\phi: \text{im } f \rightarrow \ker g$ . We say that the above is exact if  $\phi$  is an isomorphism. We say that a complex  $(C_\bullet, d)$  is exact if it is exact at all positions.

**Definition 28** (homology). Let  $(C_\bullet, d)$  be a complex. The  $n$ th homology of  $C_\bullet$  is the cokernel of the map  $\phi: \text{im } d_{n+1} \rightarrow \ker d_n$  described in [Definition 27](#), denoted  $H_n(C_\bullet)$ .

It is useful to have the following picture in mind.

$$\begin{array}{ccccccc}
 & \text{im } f & \xrightarrow{\phi} & \ker g & \longrightarrow & H_n & \\
 & \searrow i & & \downarrow & & & \\
 C_{n+1} & \xrightarrow{f} & C_n & \xrightarrow{g} & C_{n-1} & & \\
 & & \downarrow p & & \nearrow & & \\
 & & \text{coker } f & & & & 
 \end{array}$$

**Proposition 29.** Homology extends to a family of additive functors

$$H_n: \mathbf{Ch}(\mathcal{A}) \rightarrow \mathcal{A}.$$

*Proof.* We need to define  $H_n$  on morphisms. To this end, let  $f_\bullet: C_\bullet \rightarrow D_\bullet$  be a morphism of chain complexes.

$$\begin{array}{ccccc}
 C_{n+1} & \xrightarrow{d_{n+1}^C} & C_n & \xrightarrow{d_n^C} & C_{n-1} \\
 f_{n+1} \downarrow & & \downarrow f_n & & \downarrow f_{n-1} \\
 D_{n+1} & \xrightarrow{d_{n+1}^D} & D_n & \xrightarrow{d_n^D} & D_{n-1}
 \end{array}$$

We need a map  $H_n(C_\bullet) \rightarrow H_n(D_\bullet)$ . This will come from a map  $\ker d_n^C \rightarrow \ker d_n^D$ . In fact,  $f_n$  gives us such a map, essentially by restriction. We need to show that this descends to a map between cokernels.  $\square$

We can also go the other way, by defining a map

$$\iota_n: \mathcal{A} \rightarrow \mathbf{Ch}(\mathcal{A})$$

which sends an object  $A$  to the chain complex

$$\cdots \longrightarrow 0 \longrightarrow A \longrightarrow 0 \longrightarrow \cdots$$

concentrated in degree  $n$ .

**Example 30.** In some situations, homology is easy to compute explicitly. Let

$$\cdots \longrightarrow C_1 \xrightarrow{f} C_0 \longrightarrow 0$$

be a chain complex which is exact except in degree zero. Then  $H_0(C_\bullet) = \text{coker } f$ .

Similarly, if

$$0 \longrightarrow C_{-1} \xrightarrow{f} C_{-2} \longrightarrow \cdots$$

is a chain complex whose non-trivial homology is in degree 0, then  $H_0(C_\bullet) = \ker f$ .

**Definition 31** (quasi-isomorphism). Let  $f_\bullet: C_\bullet \rightarrow D_\bullet$  be a chain map. We say that  $f$  is a quasi-isomorphism if it induces isomorphisms on homology; that is, if  $H_n(f)$  is an isomorphism for all  $n$ .

Quasi-isomorphisms are a fiddly concept. Since they induce isomorphisms on homology, and isomorphisms are invertible, one might naïvely hope quasi-isomorphisms themselves were invertible. Unfortunately, we are not so lucky. Consider the following

By [Example 30](#), we

**Definition 32** (resolution). Let  $A$  be an object in an abelian category. A resolution of  $A$  consists of a chain complex  $C_\bullet$  together with a quasi-isomorphism  $C_\bullet \rightarrow \iota(A)$ .

## 4.4 Diagram lemmas

### 4.4.1 The splitting lemma

**Lemma 33** (Splitting lemma). Consider the following solid exact sequence in an abelian category  $\mathcal{A}$ .

$$0 \longrightarrow A \xrightarrow{i_A} B \xrightarrow{\pi_C} C \longrightarrow 0$$

$\nwarrow \pi_A \quad \nwarrow i_C$

The following are equivalent.

- There exists a morphism  $\pi_A: B \rightarrow A$  such that  $\pi_A \circ i_A = \text{id}_A$
- There exists a morphism  $i_C: C \rightarrow B$  such that  $\pi_C \circ i_C = \text{id}_C$
- $B$  is a direct sum  $A \oplus C$  with the obvious canonical injections and projections.

### 4.4.2 The snake lemma

**Lemma 34.** Let  $f: B \twoheadrightarrow C$  be an epimorphism, and let  $g: D \rightarrow C$  be any morphism. Then the kernel of  $f$  functions as the kernel of the pullback of  $f$  along  $g$ , in the sense that we have the following commuting diagram in which the right-hand square is a pullback square.

$$\begin{array}{ccccc} \ker f' & \xrightarrow{i} & S & \xrightarrow{f'} & D \\ \parallel & & \downarrow g' & \lrcorner & \downarrow g \\ \ker f & \xrightarrow{\iota} & B & \xrightarrow{f} & C \end{array}$$

*Proof.* Consider the following pullback square, where  $f$  is an epimorphism.

$$\begin{array}{ccc} S & \xrightarrow{f'} & D \\ g' \downarrow & \lrcorner & \downarrow g \\ B & \xrightarrow{f} & C \end{array}$$

Since we are in an abelian category, the pullback  $f'$  is also an epimorphism. Denote the kernel of  $f$  by  $K$ .

The claim is that  $K$  also functions as the kernel of  $f'$ . Of course, in order for this statement to make sense we need a map  $i: K \rightarrow S$ . This is given to us by the universal property of the pullback as follows.

$$\begin{array}{ccccc} K & & 0 & & \\ & \searrow \exists! i & & \searrow 0 & \\ & S & \longrightarrow & D & \\ & \downarrow g' & & \downarrow g & \\ & B & \xrightarrow{f} & C & \end{array}$$

Next we need to verify that  $(K, i)$  is actually the kernel of  $f'$ , i.e. satisfies the universal property. To this end, let  $v: Q \rightarrow S$  be a map such that  $f' \circ v = 0$ . We need to find a unique factorization of  $v$  through  $K$ .

$$\begin{array}{ccccc} & & Q & & \\ & \swarrow \exists! v' & \downarrow v & \searrow 0 & \\ K & \xrightarrow{i} & S & \xrightarrow{f'} & D \\ & \searrow \iota & \downarrow g' & & \downarrow g \\ & B & \xrightarrow{f} & C & \end{array}$$

By definition  $f' \circ v = 0$ . Thus,

$$\begin{aligned} f \circ g' \circ v &= g \circ f' \circ v \\ &= g \circ 0 \\ &= 0, \end{aligned}$$

so  $g' \circ v$  factors uniquely through  $K$  as  $g' \circ v = \iota \circ v'$ . It remains only to check that the triangle formed by  $v'$  commutes, i.e.  $v = v' \circ i$ . To see this, consider the following diagram, where the bottom right square is the pullback from before.

By the universal property, there exists a unique map  $Q \rightarrow S$  making this diagram commute. However, both  $v$  and  $i \circ v'$  work, so  $v = i \circ v'$ .

Thus we have shown that, in a precise sense, the kernel of an epimorphism functions as the kernel of its pullback, and we have the following commutative diagram, where the right hand square is a pullback.

$$\begin{array}{ccccc} \ker f' & \xrightarrow{i} & S & \xrightarrow{f'} & D \\ \parallel & & \downarrow g' & & \downarrow g \\ \ker f & \xrightarrow{\iota} & B & \xrightarrow{f} & C \end{array}$$

□

At least in the case that  $g$  is mono, when phrased in terms of elements, this result is more or less obvious; we can imagine the diagram above as follows.

$$\begin{array}{ccccc} \left\{ \begin{array}{l} \text{elements of pullback} \\ \text{which map to } 0 \end{array} \right\} & \hookrightarrow & \left\{ \begin{array}{l} \text{elements of } B \\ \text{which map to } C \end{array} \right\} & \twoheadrightarrow & D \\ \parallel & & \downarrow & & \downarrow \\ \left\{ \begin{array}{l} \text{elements of } B \\ \text{which map to } 0 \end{array} \right\} & \hookrightarrow & B & \twoheadrightarrow & C \end{array}$$

**Theorem 35** (snake lemma). Consider the following commutative diagram with exact

#### 4 Abelian categories

rows.

$$\begin{array}{ccccccc}
 0 & \longrightarrow & A & \xrightarrow{m} & B & \xrightarrow{e} & C \longrightarrow 0 \\
 & & \downarrow f & & \downarrow g & & \downarrow h \\
 0 & \longrightarrow & A' & \xrightarrow{m'} & B' & \xrightarrow{e'} & C' \longrightarrow 0
 \end{array}$$

This gives us an exact sequence

$$0 \rightarrow \ker f \rightarrow \ker g \rightarrow \ker h \rightarrow \operatorname{coker} f \rightarrow \operatorname{coker} g \rightarrow \operatorname{coker} h \rightarrow 0.$$

*Proof.* We provide running commentary on the diagram below.

$$\begin{array}{ccccccc}
 0 & \cdots \longrightarrow & \ker f & \cdots \longrightarrow & \ker g & \cdots \longrightarrow & \ker h \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & A & \xrightarrow{m} & B & \xrightarrow{e} & C \longrightarrow 0 \\
 & & \downarrow f & & \downarrow g & & \downarrow h \\
 0 & \longrightarrow & A' & \xrightarrow{m'} & B' & \xrightarrow{e'} & C' \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & \operatorname{coker} f & \cdots \longrightarrow & \operatorname{coker} g & \cdots \longrightarrow & \operatorname{coker} h \longrightarrow 0
 \end{array}
 \tag{4.2}$$

The dotted arrows come immediately from the universal property for kernels and cokernels, as do exactness at  $\ker g$  and  $\operatorname{coker} g$ . The argument for kernels appeared on the previous homework sheet, and the argument for cokernels is dual.

The only thing left is to define the dashed connecting homomorphism, and to prove exactness at  $\ker h$  and  $\operatorname{coker} f$ .

Extract from the data of [Diagram 4.2](#) the following diagram.

$$\begin{array}{ccccc}
 & & & & \ker h \\
 & & & & \downarrow \\
 A & \xrightarrow{m} & B & \xrightarrow{e} & C \\
 \downarrow f & & \downarrow g & & \downarrow h \\
 A' & \xrightarrow{m'} & B' & \xrightarrow{e'} & C' \\
 \downarrow & & & & \\
 \operatorname{coker} f & & & & 
 \end{array}$$

Take a pullback and a pushout, and using [Lemma 34](#) (and its dual), we find the following.

$$\begin{array}{ccccc}
 \ker u & \xhookrightarrow{a} & S & \xrightarrow{u} \twoheadrightarrow & \ker h \\
 \parallel & & \downarrow r & & \downarrow \\
 A & \xhookrightarrow{m} & B & \xrightarrow{e} \twoheadrightarrow & C \\
 f \downarrow & & \downarrow g & & \downarrow h \\
 A' & \xhookrightarrow{m'} & B' & \xrightarrow{e'} \twoheadrightarrow & C' \\
 \downarrow & & \downarrow s & & \parallel \\
 \text{coker } f & \xhookrightarrow{v} & T & \xrightarrow{b} \twoheadrightarrow & \text{coker } v
 \end{array}$$

Consider the map

$$\delta_0 = S \xrightarrow{r} B \xrightarrow{g} B' \xrightarrow{s} T .$$

By commutativity,  $\delta \circ a = 0$ , hence we get a map

$$\delta_1: \ker h \rightarrow T .$$

Composing this with  $b$  gives 0, hence we get a map

$$\delta: \text{coker } f \rightarrow \ker h .$$

□

There is another version of the snake lemma which does not have the first and last zeroes.

**Theorem 36** (snake lemma II). Given the following commutative diagram with exact rows,

$$\begin{array}{ccccccc}
 0 & \longrightarrow & A & \xrightarrow{m} & B & \xrightarrow{e} & C \longrightarrow 0 \\
 & & f \downarrow & & g \downarrow & & \downarrow h \\
 0 & \longrightarrow & A' & \xrightarrow{m'} & B' & \xrightarrow{e'} & C' \longrightarrow 0
 \end{array}$$

we get a exact sequence

$$\ker f \rightarrow \ker g \rightarrow \ker h \rightarrow \text{coker } f \rightarrow \text{coker } g \rightarrow \text{coker } h .$$

### 4.4.3 The long exact sequence on homology

**Corollary 37.** Given an exact sequence of complexes

$$0 \longrightarrow A_{\bullet} \xrightarrow{f_{\bullet}} B_{\bullet} \xrightarrow{g_{\bullet}} C_{\bullet} \longrightarrow 0$$

#### 4 Abelian categories

we get a long exact sequence on homology

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{n+1}(C) \\
 & & & & & \searrow & \delta \\
 & & & & & \swarrow & \\
 & & & & H_n(A) & \xrightarrow{H_n(f)} & H_n(B) \xrightarrow{H_n(g)} H_n(C) \\
 & & & & & \searrow & \delta \\
 & & & & & \swarrow & \\
 & & & & H_{n-1}(A) & \xrightarrow{H_{n-1}(f)} & H_{n-1}(B) \xrightarrow{H_{n-1}(g)} H_{n-1}(C) \\
 & & & & & \searrow & \delta \\
 & & & & & \swarrow & \\
 & & & & H_{n-2}(A) & \longrightarrow & \cdots
 \end{array}$$

*Proof.* For each  $n$ , we have a diagram of the following form.

$$\begin{array}{ccccccccc}
 0 & \longrightarrow & A_{n+1} & \longrightarrow & B_{n+1} & \longrightarrow & C_{n+1} & \longrightarrow & 0 \\
 & & \downarrow d_{n+1}^A & & \downarrow d_{n+1}^B & & \downarrow d_{n+1}^C & & \\
 0 & \longrightarrow & A_n & \longrightarrow & B_n & \longrightarrow & C_n & \longrightarrow & 0
 \end{array}$$

Applying the snake lemma ([Theorem 35](#)) gives us, for each  $n$ , two exact sequences as follows.

$$0 \longrightarrow \ker d_{n+1}^A \longrightarrow \ker d_{n+1}^B \longrightarrow \ker d_{n+1}^C$$

and

$$\operatorname{coker} d_n^A \longrightarrow \operatorname{coker} d_n^B \longrightarrow \operatorname{coker} d_n^C \longrightarrow 0$$

We can put these together in a diagram with exact rows as follows.

$$\begin{array}{ccccccc}
 & & \operatorname{coker} f_{n+1} & & \operatorname{coker} g_{n+1} & & \operatorname{coker} h_{n+1} & & 0 \\
 & & & & & & & & \\
 0 & & \ker f_n & & \ker g_n & & \ker h_n & & 
 \end{array}$$

Recall that for each  $n$ , we get a map

$$\phi: \operatorname{im} f_{n+1} \rightarrow \ker f_n$$

□

**Lemma 38.** Let  $\mathcal{A}$  be an abelian category, and let  $f$  be a morphism of short exact sequences in  $\mathbf{Ch}(\mathcal{A})$  as below.

$$\begin{array}{ccccccccc}
 0 & \longrightarrow & A'_\bullet & \xrightarrow{\alpha_\bullet} & A_\bullet & \xrightarrow{\alpha'_\bullet} & A''_\bullet & \longrightarrow & 0 \\
 & & \downarrow f'_\bullet & & \downarrow f_\bullet & & \downarrow f''_\bullet & & \\
 0 & \longrightarrow & B'_\bullet & \xrightarrow{\beta_\bullet} & B_\bullet & \xrightarrow{\beta'_\bullet} & B''_\bullet & \longrightarrow & 0
 \end{array}$$

This gives us the following morphism of long exact sequences on homology.

$$\begin{array}{ccccccc}
 \cdots & \longrightarrow & H_n(A) & \xrightarrow{H_n(\alpha')} & H_n(A'') & \xrightarrow{\delta} & H_{n-1}(A') & \xrightarrow{H_{n-1}(\alpha)} & H_{n-1}(A) & \longrightarrow & \cdots \\
 & & \downarrow H_n(f) & & \downarrow H_n(f'') & & \downarrow H_n(f') & & \downarrow H_n(f) & & \\
 \cdots & \longrightarrow & H_n(B) & \xrightarrow{H_n(\beta')} & H_n(B'') & \xrightarrow{\delta} & H_{n-1}(B') & \xrightarrow{H_{n-1}(\beta)} & H_{n-1}(B) & \longrightarrow & \cdots
 \end{array}$$

In particular, the connecting morphism  $\delta$  is functorial.

#### 4.4.4 The five lemma

**Lemma 39** (four lemmas). Let

$$\begin{array}{ccccccc}
 B & \longrightarrow & C & \longrightarrow & D & \longrightarrow & E \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 \Downarrow & & \downarrow & & \Downarrow & & \downarrow \\
 B' & \longrightarrow & C' & \longrightarrow & D' & \longrightarrow & E'
 \end{array}$$

be a commutative diagram with exact rows, with monomorphisms and epimorphisms as marked. Then

**Theorem 40** (five lemma).

#### 4.4.5 The nine lemma

**Theorem 41** (nine lemma).

# 5 Homological algebra in abelian categories

## 5.1 Exactness in abelian categories

**Definition 42** (exact functor). Let  $F: \mathcal{A} \rightarrow \mathcal{B}$  be an additive functor, and let

$$0 \longrightarrow A \xrightarrow{f} B \xrightarrow{g} C \longrightarrow 0$$

be an exact sequence. We use the following terminology.

- We call  $F$  left exact if

$$0 \longrightarrow F(A) \xrightarrow{f} F(B) \xrightarrow{g} F(C)$$

is exact

- We call  $F$  right exact if

$$F(A) \xrightarrow{f} F(B) \xrightarrow{g} F(C) \longrightarrow 0$$

is exact

- We call  $F$  exact if it is both left exact and right exact.

**Example 43.** We showed in [Lemma 10](#) that both hom functors  $\text{Hom}(A, -)$  and  $\text{Hom}(-, B)$  are left exact.

According to the Yoneda lemma, to check that two objects are isomorphic it suffices to check that their images under the Yoneda embedding are isomorphic. In the context of abelian categories, the following result shows that we can also check the exactness of a sequence by checking the exactness of the image of the sequence under the Yoneda embedding.

**Lemma 44.** Let  $\mathcal{A}$  be an abelian category, and let

$$A \xrightarrow{f} B \xrightarrow{g} C$$

## 5 Homological algebra in abelian categories

be objects and morphisms in  $\mathcal{A}$ . If for all  $X$  the abelian groups and homomorphisms

$$\mathrm{Hom}_{\mathcal{A}}(X, A) \xrightarrow{f_*} \mathrm{Hom}_{\mathcal{A}}(X, B) \xrightarrow{g_*} \mathrm{Hom}_{\mathcal{A}}(X, C)$$

form an exact sequence of abelian groups, then  $A \rightarrow B \rightarrow C$  is exact.

*Proof.* To see this, take  $X = A$ , giving the following sequence.

$$\mathrm{Hom}_{\mathcal{A}}(A, A) \xrightarrow{f_*} \mathrm{Hom}_{\mathcal{A}}(A, B) \xrightarrow{g_*} \mathrm{Hom}_{\mathcal{A}}(A, C)$$

Exactness implies that

$$0 = (g_* \circ f_*)(\mathrm{id}) = (g \circ f)(\mathrm{id}) = g \circ f,$$

so  $\mathrm{im} f \subset \ker g$ . Now take  $X = \ker g$ .

$$\mathrm{Hom}_{\mathcal{A}}(\ker g, A) \xrightarrow{f_*} \mathrm{Hom}_{\mathcal{A}}(\ker g, B) \xrightarrow{g_*} \mathrm{Hom}_{\mathcal{A}}(\ker g, C)$$

The canonical inclusion  $\iota: \ker g \rightarrow B$  is mapped to zero under  $g_*$ , hence is mapped to under  $f_*$  by some  $\alpha: \ker g \rightarrow A$ . That is, we have the following commuting triangle.

$$\begin{array}{ccc} & A & \\ \alpha \nearrow & & \searrow f \\ \ker g & \xrightarrow{\iota} & B \end{array}$$

Thus  $\mathrm{im} \iota = \ker g \subset \mathrm{im} f$ . □

**Proposition 45.** Let  $F: \mathcal{A} \rightarrow \mathcal{B}$  be a functor between abelian categories.

- If  $F$  preserves finite limits, then  $F$  is left exact.
- If  $F$  preserves finite colimits, then  $F$  is right exact.

*Proof.* Let  $f: A \rightarrow B$  be a morphism in an abelian category. The universal property for the kernel of  $f$  is equivalent to the following:  $(K, \iota)$  is a kernel of  $f$  if and only if the following diagram is a pullback.

$$\begin{array}{ccc} K & \longrightarrow & 0 \\ \iota \downarrow & & \downarrow \\ A & \xrightarrow{f} & B \end{array}$$

Any functor between abelian categories which preserves limits must in particular preserve pullbacks. Any such functor also sends initial objects to initial objects, and since

initial objects are zero objects, such a functor preserves zero objects. Thus, any complete functor between abelian categories takes kernels to kernels.

Dually, any functor which preserves colimits preserves cokernels.

Next, note that the exactness of the sequence

$$0 \longrightarrow A \xrightarrow{f} B \xrightarrow{g} C \longrightarrow 0$$

is equivalent to the following three conditions.

1. Exactness at  $A$  means that  $f$  is mono, i.e.  $0 \rightarrow A$  is a kernel of  $f$ .
2. Exactness at  $B$  means that  $\text{im } f = \ker g$ .
  - If  $f$  is mono, this is equivalent to demanding that  $(A, f)$  is a kernel of  $g$ .
  - If  $g$  is epi, this is equivalent to demanding that  $(C, g)$  is a cokernel of  $f$ .
3. Exactness at  $C$  means that  $g$  is epi, i.e.  $C \rightarrow 0$  is a cokernel of  $g$ .

Any functor  $G$  which is a right adjoint preserves limits. By the above reasoning,  $G$  certainly preserves zero objects and kernels. Thus,  $G$  preserves the first two conditions, which means precisely that  $G$  is left exact.

Dually, any functor  $F$  which is a left adjoint preserves colimits, hence zero objects and cokernels. Thus,  $F$  preserves the last two conditions, which means that  $F$  is right exact.  $\square$

Note that the previous theorem makes no demand that  $F$  be additive, which may seem surprising; after all, by [Definition 42](#), only exact functors are allowed the honor of being called additive. However, it turns out that a functor which preserves either finite limits or finite colimits is always additive. To see this, note that by applying any functor which is either left or right exact to a split exact sequence gives a split exact sequence.

This is often useful when trying to check the exactness of a functor which is a left or right adjoint, by the following proposition.

**Lemma 46.** Let

$$0 \longrightarrow A \xrightarrow{f} B \xrightarrow{g} C \longrightarrow 0$$

be an exact sequence, and let  $X$  be any object. Then the sequence

$$\text{Corollary 47. } 0 \longrightarrow \text{Hom}(X, A) \xrightarrow{f_*} \text{Hom}(X, B) \xrightarrow{g_*} \text{Hom}(X, C)$$

is an exact sequence of abelian groups.

*Proof.* The hom functor  $\square$

## 5.2 Chain Homotopies

**Definition 48** (chain homotopy). Let  $f_\bullet, g_\bullet: C_\bullet \rightarrow D_\bullet$  be morphisms of chain complexes. A chain homotopy

**Lemma 49.** Let  $f_\bullet, g_\bullet: C_\bullet \rightarrow D_\bullet$  be a homotopic chain complexes via a homotopy  $h$ , and let  $F$  be an additive functor. Then  $F(h)$  is a homotopy between  $F(f_\bullet)$  and  $F(g_\bullet)$ .

*Proof.* We have

$$df + fd = h,$$

so

$$F(d)F(f) + F(f)F(d) = F(h).$$

□

**Lemma 50.** Homotopy of morphisms is an equivalence relation.

*Proof.*

- Reflexivity: the zero morphism provides a homotopy between  $f \sim f$ .
- Symmetry: If  $f \stackrel{h}{\sim} g$ , then  $g \stackrel{-h}{\sim} f$
- Transitivity: If  $f \stackrel{h}{\sim} f'$  and  $f' \stackrel{h'}{\sim} f''$ , then  $f \stackrel{h+h'}{\sim} f''$ .

□

**Lemma 51.** Homotopy respects composition. That is, let  $f \stackrel{h}{\sim} g$  be homotopic morphisms, and let  $r$  be another morphism with appropriate domain and codomain.

- $f \circ r \stackrel{hr}{\sim} g \circ r$
- $r \circ f \stackrel{rh}{\sim} r \circ g$ .

*Proof.* Obvious.

□

**Definition 52** (homotopy category). Let  $\mathcal{A}$  be an abelian category. The homotopy category  $\mathcal{K}(\mathcal{A})$ , is the category whose objects are those of  $\mathbf{Ch}(\mathcal{A})$ , and whose morphisms are equivalence classes of morphisms in  $\mathcal{A}$  up to homotopy.

**Lemma 53.** The homotopy category  $\mathcal{K}(\mathcal{A})$  is an additive category, and the quotienting functor  $\mathbf{Ch}(\mathcal{A}) \rightarrow \mathcal{K}(\mathcal{A})$  is an additive functor.

*Proof.* Trivial.

□

In fact, the homotopy category satisfies the following universal property.

**Proposition 54.** Let  $F: \mathbf{Ch}(\mathcal{A}) \rightarrow \mathcal{C}$  be an additive functor such that  $\mathcal{F}(f)$  is an isomorphism for all quasi-isomorphisms  $f$ . Then there exists a unique functor  $\mathcal{K}(\mathcal{A}) \rightarrow \mathcal{C}$  making the following diagram commute.

**Proposition 55.** Let  $\mathcal{F}: \mathbf{Ch}(\mathcal{A}) \rightarrow \mathcal{B}$  be an additive functor which takes quasi-isomorphisms to isomorphisms. Then for homotopic morphisms  $f \sim g$  in  $\mathbf{Ch}(\mathcal{A})$ , we have  $F(f) = F(g)$ .

## 5.3 Projectives and injectives

**Definition 56** (projective, injective). An object  $P$  in an abelian category is said to be projective if the functor  $\mathrm{Hom}(P, -)$  is exact, and injective if  $\mathrm{Hom}(-, Q)$  is exact.

Since the hom functor  $\mathrm{Hom}(A, -)$  is left exact for every  $A$ , it is very easy to see that an object  $P$  in an abelian category  $\mathcal{A}$  is projective if for every epimorphism  $f: B \rightarrow C$  and every morphism  $p: P \rightarrow C$ , there exists a morphism  $\tilde{p}: P \rightarrow B$  such that the following diagram commutes.

$$\begin{array}{ccc} & P & \\ \exists \tilde{p} \swarrow & \downarrow p & \\ B & \xrightarrow{f} & C \end{array}$$

Dually,  $Q$  is injective if for every monomorphism  $g: A \rightarrow B$  and every morphism  $q: A \rightarrow Q$  there exists a morphism  $\tilde{q}: B \rightarrow Q$  such that the following diagram commutes.

$$\begin{array}{ccc} A & \xrightarrow{g} & B \\ q \downarrow & \nwarrow \exists \tilde{q} & \\ Q & & \end{array}$$

**Definition 57** (enough projectives). Let  $\mathcal{A}$  be an abelian category. We say that  $\mathcal{A}$  has enough projectives if for every object  $M$  there exists a projective object  $P$  and an epimorphism  $P \twoheadrightarrow M$ .

**Proposition 58.** Let

$$0 \longrightarrow A \hookrightarrow B \xrightarrow{f} P \longrightarrow 0$$

be a short exact sequence with  $P$  projective. Then the sequence splits.

*Proof.* We can add another copy of  $P$  artfully as follows.

$$\begin{array}{ccccccc} & & & & P & & \\ & & & & \downarrow \mathrm{id} & & \\ 0 & \longrightarrow & A & \hookrightarrow & B & \xrightarrow{f} & P \longrightarrow 0 \end{array}$$

By definition, we get a morphism  $P \rightarrow B$  making the triangle commute.

$$\begin{array}{ccccccc}
 & & & & P & & \\
 & & & \swarrow \exists g & \downarrow \text{id} & & \\
 0 & \longrightarrow & A & \hookrightarrow & B & \xrightarrow{f} & P \longrightarrow 0
 \end{array}$$

But this says precisely that  $f \circ g = \text{id}_P$ , i.e. the sequence splits from the right. The result follows from the splitting lemma (Lemma 33).  $\square$

**Corollary 59.** Let  $F$  be an additive functor, and let

$$0 \longrightarrow A \hookrightarrow B \xrightarrow{f} P \longrightarrow 0$$

be an exact sequence with  $P$  projective. Then  $F$  applied to the sequence gives an exact sequence.

*Proof.* Applying  $F$  to a split sequence gives a split sequence, and all split sequences are exact.  $\square$

**Corollary 60.** The category  $R\text{-Mod}$  has enough projectives.

*Proof.* By Proposition 15, free modules are projective, and every module is a quotient of a free module.  $\square$

**Proposition 61.** Let  $\mathcal{A}$  be an abelian category with enough projectives. Then every object  $A \in \mathcal{A}$  has a projective resolution.

Dually, any abelian category with enough injectives has injective resolutions.

*Proof.* We provide running commentary on the following diagram.  $\square$

**Definition 62** (projective, injective resolution). Let  $\mathcal{A}$  be an abelian category, and let  $A \in \mathcal{A}$ . A projective resolution of  $A$  is a quasi-isomorphism  $P_\bullet \rightarrow \iota(A)$ , where  $P_\bullet$  is a complex of projectives. Similarly, an injective resolution is a quasi-isomorphism  $\iota(A) \rightarrow Q_\bullet$  where  $Q_\bullet$  is a complex of injectives.

**Lemma 63.** Let  $f: P_\bullet \rightarrow \iota(M)$  be a projective resolution. Then  $f: P_0 \rightarrow M$  is an epimorphism.

*Proof.* We know that  $H_0(f): H_0(P) \rightarrow H_0(\iota(M))$  is an isomorphism. But  $H_0(\iota(M)) \simeq \iota_M$ , and that  $\square$

In fact, we can say more.

**Lemma 64.** Let  $f_\bullet: P_\bullet \rightarrow \iota(A)$  be a chain map. Then  $f$  is a projective resolution if and only if the sequence

$$\cdots P_2 \longrightarrow P_1 \longrightarrow P_0 \xrightarrow{f_0} A \longrightarrow 0$$

is exact.

**Theorem 65** (extended horseshoe lemma). Let  $\mathcal{A}$  be an abelian category with enough projectives, and let  $P'_\bullet \rightarrow M'$  and  $P''_\bullet \rightarrow M''$  be projective resolutions. Then given an exact sequence

$$0 \longrightarrow M' \xrightarrow{f} M \xrightarrow{g} M'' \longrightarrow 0$$

there is a projective resolution  $P_\bullet \rightarrow M$  and maps  $\tilde{f}$  and  $\tilde{g}$  such that the following diagram has exact rows and commutes.

$$\begin{array}{ccccccc} 0 & \longrightarrow & P'_\bullet & \xrightarrow{\tilde{f}} & P_\bullet & \xrightarrow{\tilde{g}} & P''_\bullet \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & M' & \xrightarrow{f} & M & \xrightarrow{\tilde{g}} & M'' \longrightarrow 0 \end{array}$$

Furthermore, given a morphism  $M \rightarrow N$

*Proof.* We construct  $P_\bullet$  inductively. We have specified data of the following form.

$$\begin{array}{ccccccc} & & \vdots & & \vdots & & \\ 0 & \longrightarrow & P'_1 & & P''_1 & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & P'_0 & & P''_0 & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & M' & \xrightarrow{f} & M & \xrightarrow{g} & M'' \longrightarrow 0 \end{array}$$

We define  $P_0 = P'_0 \oplus P''_0$ . We get the maps to and from  $P_0$  from the canonical injection and projection respectively.

$$\begin{array}{ccccccc} 0 & \longrightarrow & P'_0 & \xrightarrow{\iota} & P'_0 \oplus P''_0 & \xrightarrow{\pi} & P''_0 \longrightarrow 0 \\ & & \downarrow p' & \searrow f \circ p'_0 & \downarrow p & \swarrow \exists q & \downarrow p'' \\ 0 & \longrightarrow & M' & \xrightarrow{f} & M & \xrightarrow{g} & M'' \longrightarrow 0 \end{array}$$

We get the (dashed) map  $P'_0 \rightarrow M$  by composition, and the (dashed) map  $P''_0 \rightarrow M$  by projectivity of  $P''_0$  (since by [Lemma 63](#)  $p''$  is an epimorphism). From these the universal

property for coproducts gives us the (dotted) map  $p: P'_0 \oplus P''_0 \rightarrow M$ .

At this point, the innocent reader may believe that we are in the clear, and indeed many books leave it at this. Not so! We don't know that the diagram formed in this way commutes. In fact it does not; there is nothing in the world that tells us that  $q \circ \pi = p$ .

However, this is but a small transgression, since the *squares* which are formed still commute. To see this, note that we can write

$$p = f \circ p'_0 \circ \pi_{P'_0} + q \circ \pi;$$

composing this with

The snake lemma guarantees that the sequence

$$\operatorname{coker} p' \simeq 0 \longrightarrow \operatorname{coker} p \longrightarrow 0 \simeq \operatorname{coker} p''$$

is exact, hence that  $p$  is an epimorphism.

One would hope that we could now repeat this process to build further levels of  $P_\bullet$ . Unfortunately, this doesn't work because we have no guarantee that  $d_1^{P''}$  is an epimorphism, so we can't use the projectiveness of  $P''_1$  to produce a lift. We have to be clever.

The trick is to add an auxiliary row of kernels; that is, to expand the relevant portion of our diagram as follows.

$$\begin{array}{ccccccc} 0 & \longrightarrow & P'_1 & & & P''_1 & \longrightarrow 0 \\ & & \downarrow p'_1 & & & \downarrow p''_1 & \\ 0 & \longrightarrow & \ker p' & \longrightarrow & \ker p & \longrightarrow & \ker p'' \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & P'_0 & \longrightarrow & P_0 & \longrightarrow & P''_0 \longrightarrow 0 \end{array}$$

The maps  $p'_1$  and  $p''_1$  come from the exactness of  $P'_\bullet$  and  $P''_\bullet$ . In fact, they are epimorphisms, because they are really cokernel maps in disguise. That means that we are in the same situation as before, and are justified in saying “we proceed inductively”.  $\square$

**Proposition 66.** Let  $\mathcal{A}$  be an abelian category, let  $M$  and  $M'$  be objects of  $\mathcal{A}$ , and

$$P_\bullet \rightarrow M \quad \text{and} \quad P'_\bullet \rightarrow M'$$

be projective resolutions. Then for every morphism  $f: M \rightarrow M'$  there exists a lift

$\tilde{f}: P_\bullet \rightarrow P'_\bullet$  making the diagram

$$\begin{array}{ccc} P_\bullet & \xrightarrow{\tilde{f}_\bullet} & P'_\bullet \\ \downarrow & & \downarrow \\ \iota M & \xrightarrow{\iota f} & \iota M' \end{array}$$

commute, which is unique up to homotopy.

*Proof.* We construct a lift inductively.  $\square$

**Corollary 67.** For any abelian category with enough projectives, there are projective resolution functors  $\mathcal{A} \rightarrow \mathcal{K}(\mathbf{Ch}_{\geq 0}\mathcal{A})$ .

## 5.4 Mapping cones

**Definition 68** (shift functor). For any chain complex  $C_\bullet$  and any  $k \in \mathbb{Z}$ , define the  $k$ -shifted chain complex  $C_\bullet[k]$  by

$$C[k]_i = C_{k+i}; \quad d_i^{C[k]} = (-1)^k d_{i+k}^C.$$

**Definition 69** (mapping cone). Let  $f: C_\bullet \rightarrow D_\bullet$  be a chain map. Define a new complex  $\text{cone}(f)$  as follows.

- For each  $n$ , define

$$\text{cone}(f)_n = C_{n-1} \oplus D_n.$$

- Define  $d_n^{\text{cone}(f)}$  by

$$d_n^{\text{cone}(f)} = \begin{pmatrix} -d_{n-1}^C & 0 \\ -f_{n-1} & d_n^D \end{pmatrix},$$

which is shorthand for

$$d_n^{\text{cone}(f)}(x_{n-1}, y_n) = (-d_{n-1}^C x_{n-1}, d_n^D y_n - f_{n-1} x_{n-1}).$$

**Lemma 70.** The complex  $\text{cone}(f)$  naturally fits into a short exact sequence

$$0 \longrightarrow C_\bullet \xrightarrow{\iota} \text{cone}(f)_\bullet \xrightarrow{\pi} D_\bullet \longrightarrow 0.$$

*Proof.* We need to specify  $\iota$  and  $\pi$ . The morphism  $\iota$  is the usual injection; the morphism  $\pi$  is given by minus the usual projection.  $\square$

**Corollary 71.** Let  $f_\bullet: C_\bullet \rightarrow D_\bullet$  be a morphism of chain complexes. Then  $f$  is a quasi-isomorphism if and only if  $\text{cone}(f)$  is an exact complex.

## 5 Homological algebra in abelian categories

*Proof.* By [Corollary 37](#), we get a long exact sequence

$$\cdots \rightarrow H_n(X) \xrightarrow{\delta} H_n(Y) \rightarrow H_n(\text{cone}(f)) \rightarrow H_{n-1}(X) \rightarrow \cdots$$

We still need to check that  $\delta = H_n(f)$ . This is not hard to see (although I'm missing a sign somewhere); picking  $x \in \ker d^X$ , the zig-zag defining  $\delta$  goes as follows.

$$\begin{array}{ccccc} & & & x & \\ & & & \downarrow & \\ & & (x, 0) & \xrightarrow{\quad} & -x \\ & & \downarrow & & \\ f(x) & \xrightarrow{\quad} & (0, f(x)) & & \\ \downarrow & & & & \\ [f(x)] & & & & \end{array}$$

If  $\text{cone}(f)$  is exact, then we get a very short exact sequence

$$0 \longrightarrow H_n(X) \xrightarrow{H_n(f)} H_n(Y) \longrightarrow 0$$

implying that  $H_n(f)$  must be an isomorphism. Conversely, if  $H_n(f)$  is an isomorphism for all  $n$ , then the maps to and from  $H_n(\text{cone}(f))$  must be the zero maps, implying  $H_n(\text{cone}(f)) = 0$  by exactness.  $\square$

**Proposition 72.** Let  $\mathcal{A}$  be an abelian category, and let  $C_\bullet$  be a chain complex in  $\mathcal{A}$ . Let  $P_\bullet$  be a bounded below chain complex of projectives. Then any quasi-isomorphism  $g: P_\bullet \rightarrow C_\bullet$  has a quasi-inverse.

*Proof.* First we show that any morphism from a projective, bounded below complex into an exact complex is homotopic to zero. We do so by constructing a homotopy.

$$\begin{array}{ccccccc} \cdots & P_1 & \xrightarrow{\quad} & P_0 & \xrightarrow{\quad} & 0 & \cdots \\ & \downarrow & \swarrow h_1 & \downarrow & \swarrow h_0 & \downarrow & \\ \cdots & C_1 & \xrightarrow{\quad} & C_0 & \xrightarrow{\quad} & C_{-1} & \cdots \end{array}$$

Consider the following solid commuting diagram, where  $K$  is the kernel of  $d_1^C$  and  $r =$

$f_1 - h_0 \circ d_1^P$  is not the map  $f_1$ .

$$\begin{array}{ccccc}
 & & P_1 & & \\
 & \swarrow \exists h_1 & \downarrow r & \searrow 0 & \\
 & K & & & \\
 C_2 & \xrightarrow{d_2^C} & C_1 & \xrightarrow{d_1^C} & C_0
 \end{array}$$

Because

$$\begin{aligned}
 d_1^C \circ r &= d_1^C \circ f_1 - d_1^C \circ h_0 \circ d_1^P \\
 &= d_1^C \circ f_1 - d_1^C \circ f_1 \\
 &= 0,
 \end{aligned}$$

the morphism  $r$  factors through  $K$ . This gives us a morphism from a projective onto the target of an epimorphism, which we can lift to the source. This is what we call  $h_1$ .

It remains to check that  $h_1$  is a homotopy from  $f$  to 0. Plugging in, we find

$$\begin{aligned}
 d_2^C \circ h_1 + h_0 \circ d_1^P &= r + h_0 \circ d_1^P \\
 &= f_1
 \end{aligned}$$

as required.

Iterating this process, we get a homotopy between 0 and  $f$ .

Now let  $f: C_\bullet \rightarrow P_\bullet$  be a quasi-isomorphism, where  $P_\bullet$  is a bounded-below projective complex. Since  $f$  is a quasi-isomorphism,  $\text{cone}(f)$  is exact, which means that  $\iota: P \rightarrow \text{cone}(f)$  is homotopic to the zero morphism.

$$\begin{array}{ccccc}
 P_{i+1} & \xrightarrow{d_{i+1}^P} & P_i & \xrightarrow{d_i^P} & P_{i-1} \\
 \downarrow \iota_{i+1} & \searrow \tilde{h}_i & \downarrow \iota_i & \searrow \tilde{h}_{i-1} & \downarrow \iota_{i-1} \\
 C_i \oplus P_{i+1} & \xrightarrow{d_{i+1}^{\text{cone}(f)}} & C_{i-1} \oplus P_i & \xrightarrow{d_i^{\text{cone}(f)}} & C_{i-2} \oplus P_{i-1}
 \end{array}$$

That is, there exist  $\tilde{h}_i: P_i \rightarrow \text{cone}(f)_{i+1}$  such that

$$d_{i+1}^{\text{cone}(f)} \circ \tilde{h}_i + \tilde{h}_{i-1} \circ d_i^P = \iota. \quad (5.1)$$

Writing  $\tilde{h}_i$  in components as  $\tilde{h}_i = (\beta_i, \gamma_i)$ , where

$$\beta_i: P_i \rightarrow C_i \quad \text{and} \quad \gamma_i: P_{i-1} \rightarrow P_i,$$

we find what looks tantalizingly like a chain map  $\beta_\bullet: P_\bullet \rightarrow C_\bullet$ . Indeed, writing [Equation 5.1](#) in components, we find the following.

$$\begin{pmatrix} -d_i^C & 0 \\ -f_i & d_{i+1}^P \end{pmatrix} \begin{pmatrix} \beta_i \\ \gamma_i \end{pmatrix} + \begin{pmatrix} \beta_{i-1} \\ \gamma_{i-1} \end{pmatrix} \begin{pmatrix} d_i^P \\ \end{pmatrix} = \begin{pmatrix} 0 \\ \text{id}_{P_i} \end{pmatrix}$$

$$\begin{pmatrix} -d_i^C \circ \beta_i + \beta_{i-1} \circ d_i^P \\ -f_i \circ \beta_i + d_{i+1}^P \circ \gamma_i + \gamma_{i-1} \circ d_i^P \end{pmatrix} = \begin{pmatrix} 0 \\ \text{id}_{P_i} \end{pmatrix}$$

The first line tells us that  $\beta$  is a chain map. The second line tells us that<sup>1</sup>

$$d_{i+1}^P \circ \gamma_i + \gamma_{i-1} \circ d_i^P = \text{id}_{P_i} - f_i \circ \beta_i,$$

i.e. that  $\gamma$  is a homotopy  $\text{id}_{P_i} \sim f_i \circ \beta_i$ . But homology collapses homotopic maps, so

$$H_n(\text{id}_{P_i}) = H_n(f_i) \circ H_n(\beta_i),$$

which implies that

$$H_n(\beta_i) = H_n(f_i)^{-1}.$$

□

## 5.5 Localization at weak equivalences: a love story

We can embed any abelian category  $\mathcal{A}$  into the corresponding category  $\text{Ch}(\mathcal{A})$  of chain complexes via inclusion into degree zero. This is obviously a lossless procedure, in the sense that we recover  $\mathcal{A}$  by restricting to degree 0.

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\iota} & \text{Ch}(\mathcal{A}) \\ & \xleftarrow{(-)_0} & \end{array}$$

Equivalently, we recover our category  $\mathcal{A}$  by taking zeroth homology.

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\iota} & \text{Ch}(\mathcal{A}) \\ & \xleftarrow{H_0} & \end{array}$$

However, we notice that there are much better-behaved embeddings of  $\mathcal{A}$  into  $\text{Ch}(\mathcal{A})$  such that we recover  $\mathcal{A}$  when taking zeroth homology. For example, taking projective resolutions of objects and lifting morphisms using [Proposition 66](#) will do the trick. Unfortunately, this is not in general uniquely defined: one can take many different pro-

<sup>1</sup>Actually, it doesn't tell us this, but I suspect that it would if I were a little better at algebra.

jective resolutions, and lift morphisms in many different ways. There is no reason to expect these data to assemble themselves functorially.

However, if we were to modify  $\mathbf{Ch}(\mathcal{A})$  in such a way that all quasi-isomorphisms became bona-fide isomorphisms, then we would have this functoriality, thanks to [Proposition 55](#).

Thus we find ourselves in a common situation: we have a category  $\mathbf{Ch}(\mathcal{A})$ , and identified a collection of morphisms inside this category which we would like to view as weak equivalences, namely the quasi-isomorphisms. In an ideal world, we would simply promote quasi-isomorphisms to bona fide isomorphisms. That is, we would like to form the localization

$$\mathbf{Ch}(\mathcal{A}) \rightarrow \mathbf{Ch}(\mathcal{A})[\{\text{quasi-isomorphisms}\}^{-1}].$$

Unfortunately, localization is not at all a trivial process, and one can get hurt if one is not careful. For that reason, actually constructing the above localization and then working with it is not a profitable approach to take.

However, note that we can get what we want by making a more draconian identification: collapsing all homotopy equivalences. Homotopy equivalence is friendlier than quasi-isomorphism in the sense that one can take the quotient by it; that is, there is a well-defined additive functor

$$\mathbf{Ch}(\mathcal{A}) \twoheadrightarrow \mathcal{K}(\mathcal{A})$$

which is the identity on objects and sends morphisms to their equivalence classes modulo homotopy; this sends precisely homotopy equivalences to isomorphisms. In fact, this is universal in the sense that every other additive functor sending quasi-isomorphisms to isomorphisms factors through it. In particular, the functor

$$\mathbf{Ch}(\mathcal{A}) \rightarrow \mathbf{Ch}(\mathcal{A})[\{\text{quasi-isomorphisms}\}^{-1}]$$

factors through it.

But now we are in a really wonderful position, as long as  $\mathcal{A}$  has enough projectives: we can (by REF we have already proved) find a projective resolution functor

$$P: \mathcal{A} \rightarrow \mathcal{K}^+(\mathcal{A}).$$

In fact, this functor is an equivalence of categories.

## 5.6 Homological $\delta$ -functors and derived functors

We have noticed that we can

**Definition 73** (derived functor). Let  $F: \mathcal{A} \rightarrow \mathcal{B}$  be a functor between abelian categories.

- If  $F$  is right exact and  $\mathcal{A}$  has enough projectives, we declare the left derived functor to be the cohomological  $\delta$ -functor  $\{L_n F\}$  defined by

$$L_n F = \mathcal{A} \xrightarrow{P} \mathcal{K}(\mathbf{Ch}_{\geq 0}(\mathcal{A})) \xrightarrow{F} \mathcal{K}(\mathbf{Ch}_{\geq 0}(\mathcal{B})) \xrightarrow{H_n} \mathcal{B}$$

where  $P: \mathcal{A} \rightarrow \mathcal{K}(\mathbf{Ch}_{\geq 0}(\mathcal{A}))$  is a projective resolution functor.

- If  $F$  is left exact and  $\mathcal{A}$  has enough injectives, we define the right derived functor to be the cohomological  $\delta$ -functor

$$R^n F(X) = H^n \circ F \circ Q$$

where  $Q$  is an injective resolution functor.

It may seem that we still have something left to prove; after all, we have not shown that the result of our composition is independant of the projective/injective resolution functor we used. However,

Because  $\{H_n\}$  is a homological  $\delta$ -functor, it is trivial that  $L_n F$  is a homological delta-functor. Note that it really does extend  $F$  in the following sense.

**Proposition 74.** Let  $F: \mathcal{A} \rightarrow \mathcal{B}$  be a right exact functor between abelian categories. We have that

$$L_0 F \simeq F.$$

*Proof.* Let  $P_\bullet \rightarrow X$  be a projective resolution. By [Lemma 64](#), the following sequence is exact.

$$P_2 \longrightarrow P_1 \xrightarrow{f} P_0 \twoheadrightarrow X \longrightarrow 0$$

Since  $F$  is right exact, the following sequence is exact.

$$F(P_2) \longrightarrow F(P_1) \xrightarrow{F(f)} F(P_0) \twoheadrightarrow F(X) \longrightarrow 0$$

This tells us that  $F(X) \simeq \text{coker}(F(f))$ . But

$$\text{coker}(H(f)) \simeq H_0(P_\bullet) = L_0 F(X).$$

Similarly, on morphisms □

**Definition 75** (homological  $\delta$ -functor). A homological  $\delta$ -functor between abelian categories  $\mathcal{A}$  and  $\mathcal{B}$  consists of the following data.

1. For each  $n \in \mathbb{Z}$ , an additive functor

$$T_n: \mathcal{A} \rightarrow \mathcal{B}.$$

2. For every short exact sequence

$$0 \longrightarrow A \longrightarrow B \longrightarrow C \longrightarrow 0$$

in  $\mathcal{A}$  and for each  $n \in \mathbb{Z}$ , a morphism

$$\delta_n: T_n(C) \rightarrow T_{n-1}(A).$$

This data is subject to the following conditions.

1. For  $n < 0$ , we have  $T_n = 0$ .
2. For every short exact sequence as above, there is a long exact sequence

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & T_{n+1}(C) \\
 & & & & & \searrow & \delta \\
 & & & & & & \curvearrowright \\
 & & & T_n(A) & \xrightarrow{T_n(f)} & T_n(B) & \xrightarrow{T_n(g)} & T_n(C) \\
 & & & & & \searrow & \delta \\
 & & & & & & \curvearrowright \\
 & & & T_{n-1}(A) & \xrightarrow{T_{n-1}(f)} & T_{n-1}(B) & \xrightarrow{T_{n-1}(g)} & T_{n-1}(C) \\
 & & & & & \searrow & \delta \\
 & & & & & & \curvearrowright \\
 & & & T_{n-2}(A) & \longrightarrow & \cdots & & 
 \end{array}$$

3. For every morphism of short exact sequences

$$\begin{array}{ccccccccc}
 0 & \longrightarrow & A & \longrightarrow & B & \longrightarrow & C & \longrightarrow & 0 \\
 & & f \downarrow & & g \downarrow & & h \downarrow & & \\
 0 & \longrightarrow & A' & \longrightarrow & B' & \longrightarrow & C' & \longrightarrow & 0
 \end{array}$$

and every  $n$ , the diagram

$$\begin{array}{ccc}
 T_n(C) & \xrightarrow{\delta_n} & T_{n-1}(A) \\
 T_n(h) \downarrow & & \downarrow T_n(f) \\
 T_n(C') & \xrightarrow{\delta_n} & T_{n-1}(A')
 \end{array}$$

commutes; that is, a morphism of short exact sequences leads to a morphism of long exact sequences.

This seems like an inelegant definition, and indeed it is.

**Definition 76** (cohomological  $\delta$ -functors). Dual to [Definition 75](#).

**Example 77.** The prototypical example of a homological  $\delta$ -functor is homology: the collection  $H_n: \mathbf{Ch}(\mathcal{A}) \rightarrow \mathcal{A}$ , together with the collection of connecting homomorphisms,

is a homological delta-functor. In fact, the most interesting homological delta functors called *derived functors*, come from homology.

## 5.7 Double complexes

**Definition 78** (double complex). Let  $\mathcal{A}$  be an abelian category. A double complex in  $\mathcal{A}$  consists of an array  $M_{i,j}$  of objects together with, for every  $i$  and  $j \in \mathbb{Z}$ , morphisms

$$d_{i,j}: M_{i,j} \rightarrow M_{i-1,j}, \quad \delta_{i,j}: M_{i,j} \rightarrow M_{i,j-1}$$

subject to the following conditions.

- $d^2 = 0$
- $\delta^2 = 0$
- $d\delta + \delta d = 0$

We say that  $M_{\bullet,\bullet}$  is first-quadrant if  $M_{i,j} = 0$  for  $i, j < 0$ .

That is, for  $M$  a double complex the following diagram anticommutes rather than commutes.

$$\begin{array}{ccccccc} M_{0,3} & \longleftarrow & M_{1,3} & \longleftarrow & M_{2,3} & \longleftarrow & M_{3,3} \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ M_{0,2} & \longleftarrow & M_{1,2} & \longleftarrow & M_{2,2} & \longleftarrow & M_{3,2} \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ M_{0,1} & \longleftarrow & M_{1,1} & \longleftarrow & M_{2,1} & \longleftarrow & M_{3,1} \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ M_{0,0} & \longleftarrow & M_{1,0} & \longleftarrow & M_{2,0} & \longleftarrow & M_{3,0} \end{array}$$

Given any complex of complexes

$$\left( \cdots \longrightarrow M_{1,\bullet} \longrightarrow M_{0,\bullet} \longrightarrow M_{-1,\bullet} \longrightarrow \cdots \right) \in \mathbf{Ch}(\mathbf{Ch}(\mathcal{A})),$$

one can construct a double complex by multiplying every other differential by  $-1$ .

**Definition 79** (total complex). Let  $M_{\bullet,\bullet}$  be a first-quadrant<sup>2</sup> double complex. The total

<sup>2</sup>This restriction is not strictly necessary, but then one has to deal with infinite direct sums, and hence must decide whether one wants the direct sum or the direct product. We only need first-quadrant double complexes, so all of our sums will be finite.

complex  $\text{Tot}(M)_\bullet$  is defined level-wise by

$$\text{Tot}(M)_n = \bigoplus_{i+j=n} M_{i,j},$$

with differential given by  $d_{\text{Tot}} = d + \delta$ .

**Lemma 80.** The total complex really is a complex, i.e.

$$d_{\text{Tot}} \circ d_{\text{Tot}} = 0.$$

*Proof.* Hand-wavily, we have

$$d_{\text{Tot}} \circ d_{\text{Tot}} = (d + \delta) \circ (d + \delta) = d^2 + d \circ \delta + \delta \circ d + \delta^2 = 0.$$

□

**Theorem 81.** Let  $M_{i,j}$  be a first-quadrant double complex. Then if either the rows  $M_{\bullet,j}$  or the columns  $M_{i,\bullet}$  are exact, then the total complex  $\text{Tot}(M)_\bullet$  is exact.

*Proof.* Let  $M_{i,j}$  be a first-quadrant double complex, without loss of generality with exact rows.

$$\begin{array}{ccccccc} & & M_{3,0} & & & & \\ & & \downarrow d_{3,0} & & & & \\ & M_{2,0} & \xleftarrow{\delta_{2,1}} & M_{2,1} & & & \\ & \downarrow d_{2,0} & & \downarrow d_{2,1} & & & \\ & M_{1,0} & \xleftarrow{\delta_{1,1}} & M_{1,1} & \xleftarrow{\delta_{1,2}} & M_{1,2} & \\ & \downarrow d_{1,0} & & \downarrow d_{1,1} & & \downarrow d_{1,2} & \\ M_{0,0} & \xleftarrow{\delta_{0,1}} & M_{0,1} & \xleftarrow{\delta_{0,2}} & M_{0,2} & \xleftarrow{\delta_{0,3}} & M_{0,3} \end{array}$$

We want to show that the total complex

$$\begin{array}{ccc} M_{3,0} \oplus M_{2,1} \oplus M_{1,2} \oplus M_{0,3} & = & \text{Tot}(M)_3 \\ \downarrow & & \downarrow \\ M_{2,0} \oplus M_{1,1} \oplus M_{0,2} & = & \text{Tot}(M)_2 \\ \downarrow & & \downarrow \\ M_{1,0} \oplus M_{0,1} & = & \text{Tot}(M)_1 \\ \downarrow & & \downarrow \\ M_{0,0} & = & \text{Tot}(M)_0 \\ \downarrow & & \downarrow \\ 0 & & 0 \end{array}$$

## 5 Homological algebra in abelian categories

is exact.

The construction is inductive on the degree of the total complex. At level 0 there is nothing to show; the morphism  $d_1^{\text{Tot}}$  is manifestly surjective since  $\delta_{0,1}$  is. Since numbers greater than 1 are for all intents and purposes interchangeable, we construct the inductive step for  $n = 2$ .

We have a triple  $m = (m_{2,0}, m_{1,1}, m_{0,2}) \in \text{Tot}(M)_2$  which maps to 0 under  $d_2^{\text{Tot}}$ ; that is,

$$d_{2,0}m_{2,0} + \delta_{1,1}m_{1,1} = 0, \quad d_{1,1}m_{1,1} + \delta_{0,2}m_{0,2} = 0.$$

Our goal is to find

$$n = (n_{3,0}, n_{2,1}, n_{1,2}, n_{0,3}) \in \text{Tot}(M)_3$$

such that  $d_3^{\text{Tot}}n = m$ .

We make our lives easier by choosing  $n_{3,0} = 0$ . By exactness, we can always find  $n_{2,1}$  such that  $\delta n_{2,1} = m_{2,0}$ . Thus, by anti-commutativity,

$$d\delta n_{2,1} = -\delta dn_{2,1}.$$

But  $\delta n_{2,1} = m_{2,0} = -\delta m_{1,1}$ , so

$$\delta(m_{1,1} - dn_{2,1}) = 0.$$

This means that  $m_{1,1} - dn_{2,1} \in \ker \delta$ , i.e. that there exists  $n_{1,2}$  such that  $\delta n_{1,2} = m_{1,1} - dn_{2,1}$ . Thus

$$d\delta n_{1,2} = dm_{1,1} = -\delta m_{0,2}.$$

But

$$d\delta n_{1,2} = -\delta dn_{1,2},$$

so

$$\delta(m_{0,2} - dn_{1,2}) = 0.$$

Now we repeat this process, finding  $n_{0,3}$  such that

$$\delta n_{1,2} = m_{1,1} - dn_{2,1},$$

and  $n_{0,3}$  such that

$$\delta n_{0,3} = m_{0,2} - dn_{1,2}.$$

Then

$$\begin{aligned} d^{\text{Tot}}(n_{3,0} + n_{2,1} + n_{1,2} + n_{0,3}) &= 0 + (d + \delta)n_{2,1} + (d + \delta)n_{1,2} + (d + \delta)n_{0,3} \\ &= 0 + 0 + m_{2,0} + dn_{2,1} + (m_{1,1} - dn_{2,1}) + dn_{1,2} + (m_{0,2} - dn_{1,2}) + 0 \\ &= m_{2,0} + m_{1,1} + m_{0,2} \end{aligned}$$

as required.  $\square$

Consider any morphism  $\alpha$  in  $\mathbf{Ch}_{\geq 0}(\mathbf{Ch}_{\geq 0}(\mathcal{A}))$  to a complex concentrated in degree 0. We can view this in two ways.

- As a chain

$$C_{2,\bullet} \longrightarrow C_{1,\bullet} \longrightarrow C_{0,\bullet} \xrightarrow{\alpha} D_{\bullet}$$

hence (by inserting appropriate minus signs) a double complex  $C_{\bullet,\bullet}^D$ ;

- As a morphism between double complexes, hence between totalizations

$$\mathrm{Tot}(\alpha)_{\bullet}: \mathrm{Tot}(C)_{\bullet} \rightarrow \mathrm{Tot}(D)_{\bullet}.$$

**Lemma 82.** These two points of view agree in the sense that

$$\mathrm{Tot}(C^D) = \mathrm{Cone}(\mathrm{Tot}(\alpha)).$$

*Proof.* Write down the definitions.  $\square$

**Theorem 83.** Let  $A_{\bullet} \in \mathbf{Ch}_{\geq 0}(\mathcal{A})$ , and let

$$\begin{array}{ccccccc} \cdots & \longrightarrow & M_{2,\bullet} & \longrightarrow & M_{1,\bullet} & \longrightarrow & M_{0,\bullet} \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \alpha_{\bullet} \\ \cdots & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & A_{\bullet} \end{array}$$

be a resolution of  $A_{\bullet}$ . Then  $\mathrm{Tot}(M)$  is quasi-isomorphic to  $A$ .

*Proof.* The sequence

$$\cdots \longrightarrow M_{2,\bullet} \longrightarrow M_{1,\bullet} \longrightarrow M_{0,\bullet} \longrightarrow A_{\bullet} \longrightarrow 0$$

is exact. By [Theorem 81](#), the total complex  $\mathrm{Tot}(M^A)$  is exact. But by [Lemma 82](#) the total complex is equivalently the cone of  $\alpha_{\bullet}$ . However, we have seen (in [Corollary 71](#)) that exactness of  $\mathrm{cone}(\alpha_{\bullet})$  means that  $\alpha_{\bullet}$  is a quasi-isomorphism.  $\square$

**Corollary 84.** Let

$$\cdots \longrightarrow M_{2,\bullet} \longrightarrow M_{1,\bullet} \longrightarrow M_{0,\bullet} \longrightarrow 0$$

be a complex in  $\mathbf{Ch}_{\geq 0}(\mathbf{Ch}_{\geq 0}(\mathcal{A}))$  such that  $H_0(M_{i,\bullet}) = 0$  for  $i \neq 0$ . Then  $\mathrm{Tot}(M)$  is quasi-isomorphic to the sequence

$$\cdots \longrightarrow H_0(M_{2,\bullet}) \longrightarrow H_0(M_{1,\bullet}) \longrightarrow H_0(M_{0,\bullet}) \longrightarrow 0$$

## 5 Homological algebra in abelian categories

*Proof.* For each  $i$  we can write

$$H_0(M_{i,\bullet}) = \text{coker } d_1^{M_i}.$$

In particular, we have a double complex

$$\begin{array}{ccccccc}
 M_{0,3} & \longleftarrow & M_{1,3} & \longleftarrow & M_{2,3} & \longleftarrow & M_{3,3} \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 M_{0,2} & \longleftarrow & M_{1,2} & \longleftarrow & M_{2,2} & \longleftarrow & M_{3,2} \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 M_{0,1} & \longleftarrow & M_{1,1} & \longleftarrow & M_{2,1} & \longleftarrow & M_{3,1} \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 M_{0,0} & \longleftarrow & M_{1,0} & \longleftarrow & M_{2,0} & \longleftarrow & M_{3,0} \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 H_0(M_{0,\bullet}) & \longleftarrow & H_0(M_{1,\bullet}) & \longleftarrow & H_0(M_{2,\bullet}) & \longleftarrow & H_0(M_{3,\bullet}) \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 0 & & 0 & & 0 & & 0
 \end{array}$$

Flipping along the main diagonal, we have the following resolution.

$$M_{\bullet,2} \longrightarrow M_{\bullet,1} \longrightarrow M_{\bullet,0} \longrightarrow H_0(M_{\bullet,\bullet})$$

Now [Theorem 83](#) gives us the result we want. □

## 5.8 Tensor-hom adjunction for chain complexes

In a general abelian category, there is no notion of a tensor product. However, many interesting abelian categories carry tensor products, and we would like to be able to talk about them. In this section, we let  $\mathcal{A}$  be an abelian category and let

$$- \otimes -: \mathcal{A}^{\text{op}} \otimes \mathcal{A} \rightarrow \mathcal{H},$$

be an additive functor, where  $\mathcal{H}$  is some abelian category equipped with an exact functor to  $\mathbf{Ab}$ . Further suppose that

**Definition 85** (tensor product of chain complexes). Let  $C_\bullet, D_\bullet$  be chain complexes in  $\mathcal{A}$ . We define the tensor product of  $C_\bullet$  and  $D_\bullet$  by

$$(C \otimes D)_\bullet = \text{Tot}(C_\bullet \otimes D_\bullet),$$

where  $\text{Tot}(C_\bullet \otimes D_\bullet)$  is the totalization of the double complex  $C_\bullet \otimes D_\bullet$ .

**Definition 86** (internal hom). Let  $\mathcal{A}$  be an abelian category with an internal hom functor (for example, a category of modules over a commutative ring), and let  $C_\bullet, D_\bullet$  be chain complexes in  $\mathcal{A}$ . We have

## 5.9 The Künneth formula

This section takes place in  $R\text{-Mod}$ , where  $R$  is a PID. For example, everything we are saying holds in **Ab**.

**Lemma 87.** Let  $C_\bullet$  be a chain complex of free  $R$ -modules with trivial differential, and let  $C'_\bullet$  be an arbitrary chain complex. Then there is an isomorphism

$$\lambda: \bigoplus_{p+q=n} H_p(C_\bullet) \otimes H_q(C'_\bullet) \cong H_n(C_\bullet \otimes C'_\bullet).$$

*Proof.* We write

$$Z_p = Z_p(C_\bullet), \quad B_p = B_p(C_\bullet), \quad Z'_p = Z_p(C'_\bullet), \quad B'_p = B_p(C'_\bullet),$$

The sequence

$$0 \longrightarrow Z'_q \hookrightarrow C'_q \twoheadrightarrow B'_{q-1} \longrightarrow 0$$

is exact by definition, and since  $Z_p = C_p$  is by assumption free, the sequence

By definition,  $Z_p = C_p$  is free. Thus the sequence

$$0 \longrightarrow Z_p \otimes Z'_q \hookrightarrow Z_p \otimes C'_q \twoheadrightarrow Z_p \otimes B'_{q-1} \longrightarrow 0$$

is exact.

The differential of the tensor product complex  $C_\bullet \otimes C'_\bullet$  is

$$\begin{aligned} d_n^{\text{tot}} &= \sum_{i=0}^n d_i^C \otimes \text{id}_{C'_{n-i}} + (-1)^i \text{id}_{C_i} \otimes d_{n-i}^{C'} \\ &= \sum_{i=0}^n (-1)^i \text{id}_{C_i} \otimes d_{n-i}^C. \end{aligned}$$

Since  $C_i$  is by assumption free, tensoring with it doesn't change homology, and we have

$$Z_n(C_\bullet \otimes C'_\bullet) = \bigoplus_{p+q=n} Z_p \otimes Z'_q,$$

## 5 Homological algebra in abelian categories

and

$$Z_n(C_\bullet \otimes C'_\bullet) = \bigoplus_{p+q=n} Z_p \otimes Z'_q,$$

□

## 6 Basic applications

### 6.1 The Tor functor

Let  $R$  be a ring, and  $N$  a right  $R$ -module. There is an adjunction

$$- \otimes_R N : \mathbf{Mod}\text{-}R \leftrightarrow \mathbf{Ab} : \text{Hom}(N, -).$$

Thus, the functor  $- \otimes_R N$  preserves colimits, hence by [Proposition 45](#), is right exact. Thus, we may form the left derived functor.

**Definition 88** (Tor functor). The left derived functor of  $- \otimes_R N$ , is called the Tor functor and denoted

$$\text{Tor}_i^R(-, N).$$

**Example 89.** Let  $R$  be a ring, and let  $r \in R$ . Assume that left multiplication by  $r$  is injective, and consider the right  $R$ -module  $R/rR$ . We have the short exact sequence

$$0 \longrightarrow R \xrightarrow{r \cdot} R \xrightarrow{\pi} R/rR \longrightarrow 0$$

exhibiting

$$0 \longrightarrow R \xrightarrow{r \cdot} R \longrightarrow 0$$

as a free resolution of  $R/rR$ . Thus we can calculate

$$\text{Tor}_i^R(R/rR, N) \simeq H_i \left( 0 \longrightarrow R \otimes_R N \xrightarrow{r \cdot} R \otimes_R N \longrightarrow 0 \right)$$

That is, we have

$$\text{Tor}_i^R(R/rR, N) \simeq \begin{cases} N/rN, & n = 0 \\ rN, & n = 1 \\ 0, & \text{otherwise.} \end{cases}$$

There is a worrying asymmetry to our definition of Tor. The tensor product is, morally speaking, symmetric; that is, it should not matter whether we derive the first factor or the second. Pleasingly, Tor respects this.

**Proposition 90.** The functor Tor is balanced; that is,

$$L_i \text{Hom}(M, -)(N) \simeq L_i \text{Hom}(-, N)(M).$$

## 6.2 Ext and extensions

## 6.3 Group (co)homology

### 6.3.1 The Dold-Kan correspondence

The Dold-Kan correspondence, and its stronger, better-looking cousin the Dold-Puppe correspondence, tell us roughly that studying bounded-below chain complexes is the same as studying simplicial objects.

Let  $A: \Delta^{\text{op}} \rightarrow \mathbf{Ab}$  be a simplicial abelian group, and define

$$NA_n = \bigcap_{i=0}^{n-1} \ker(d_i) \subset A_n.$$

This becomes a chain complex when given the differential  $(-1)^n d_n$ . This is easy to see; we have

$$d_{n-1} \circ d_n = d_{n-1} \circ d_{n-1},$$

and the domain of this map is contained in  $\ker d_{n-1}$ .

**Definition 91** (normalized chain complex). Let  $A: \Delta^{\text{op}} \rightarrow \mathbf{Ab}$  be a simplicial abelian group. The normalized chain complex of  $A$  is the following chain complex.

$$\cdots \xrightarrow{(-1)^{n+2} d_{n+2}} NA_{n+1} \xrightarrow{(-1)^{n+1} d_{n+1}} NA_n \xrightarrow{(-1)^n d_n} NA_{n-1} \xrightarrow{(-1)^{n-1} d_{n-1}} \cdots$$

**Definition 92** (Moore complex). Let  $A: \Delta^{\text{op}} \rightarrow \mathbf{Ab}$  be a simplicial abelian group. The Moore complex of  $A$  is the chain complex with  $n$ -chains  $A_n$  and differential

$$\partial = \sum_{i=0}^n (-1)^i d_i.$$

This is a bona fide chain complex due to the following calculation.

$$\begin{aligned}
 \partial^2 &= \left( \sum_{j=0}^{n-1} (-1)^j d_j \right) \circ \left( \sum_{i=0}^n (-1)^i d_i \right) \\
 &= \sum \sum (-1)^{i+j} d_j \circ d_i \\
 &= \sum_{0 \leq j < i \leq n} (-1)^{i+j} d_j \circ d_i + \sum_{0 \leq i \leq j \leq n-1} (-1)^{i+j} d_j \circ d_i \\
 &= \sum_{0 \leq j < i \leq n} (-1)^{i+j} d_{i-1} \circ d_j + \sum_{0 \leq i \leq j \leq n-1} (-1)^{i+j} d_j \circ d_i \\
 &= 0.
 \end{aligned}$$

Following Goerss-Jardine, we denote the Moore complex of  $A$  simply by  $A$ , unless this is confusing. In this case, we will denote it by  $MA$ .

**Definition 93** (alternating face maps chain modulo degeneracies). Denote by  $DA_n$  the subgroup of  $A_n$  generated by degenerate simplices. Since  $\partial: A_n \rightarrow A_{n-1}$  takes degenerate simplices to linear combinations of degenerate simplices, it descends to a chain map.

$$\cdots \xrightarrow{[\partial]} A_{n+1}/DA_{n+1} \xrightarrow{[\partial]} A_n/DA_n \xrightarrow{[\partial]} A_{n-1}/DA_{n-1} \xrightarrow{[\partial]} \cdots$$

We denote this chain complex by  $A/D(A)$ , and call it the alternating face maps chain modulo degeneracies.<sup>1</sup>

**Lemma 94.** We have the following map of chain complexes, where  $i$  is inclusion and  $p$  is projection.

$$NA \xhookrightarrow{i} A \twoheadrightarrow^p A/D(A)$$

*Proof.* We need only show that the following diagram commutes.

$$\begin{array}{ccccc}
 NA_n & \hookrightarrow & A_n & \twoheadrightarrow & A_n/DA_n \\
 (-1)^n d_n \downarrow & & \downarrow \partial & & \downarrow [\partial] \\
 NA_{n-1} & \hookrightarrow & A_{n-1} & \twoheadrightarrow & A_{n-1}/DA_{n-1}
 \end{array}$$

The left-hand square commutes because all differentials except  $d_n$  vanish on everything in  $NA_n$ , and the right-hand square commutes trivially.  $\square$

**Theorem 95.** The composite

$$p \circ i: NA \rightarrow A/D(A)$$

is an isomorphism of chain complexes.

<sup>1</sup>The nLab is responsible for this terminology.

Let  $f: [m] \rightarrow [n]$  be a morphism in the simplex category  $\Delta$ . By functoriality,  $f$  induces a map

$$N\Delta^n \rightarrow N\Delta^m.$$

In fact, this map is rather simple. Take, for example,  $f = d_0: [n] \rightarrow [n-1]$ . By definition, this map gives

We define a simplicial object

$$\mathbb{Z}[-]: \Delta \rightarrow \mathbf{Ch}_+(\mathbf{Ab})$$

on objects by

$$[n] \mapsto N\mathcal{F}(\Delta^n),$$

and on morphisms by

$$f: [m] \rightarrow [n] \mapsto$$

which takes each object  $[n]$  to the corresponding normalized complex on the free abelian group on the corresponding simplicial set.

We then get a nerve and realization

$$N: \mathbf{Ab}_\Delta \longleftrightarrow \mathbf{Ch}_+(\mathbf{Ab}) : \Gamma. \quad (6.1)$$

**Theorem 96.** The adjunction in Equation 6.1 is an equivalence of categories

*Proof.* later, if I have time. □

Also later if time, Dold-Puppe correspondence: this works not only for  $\mathbf{Ab}$ , but for any abelian category.

### 6.3.2 The bar construction

This section assumes a basic knowledge of simplicial sets. We will denote by  $\bar{\Delta}$  the extended simplex category, i.e. the simplex category which includes  $[-1] = \emptyset$ .

Let  $\mathcal{C}$  and  $\mathcal{D}$  be categories, and

$$L: \mathcal{C} \leftrightarrow \mathcal{D} : R$$

an adjunction with unit  $\eta: \text{id}_{\mathcal{C}} \rightarrow RL$  and counit  $\epsilon: LR \rightarrow \text{id}_{\mathcal{D}}$ .

Recall that this data gives a comonad in  $\mathcal{D}$ , i.e. a comonoid internal to the category  $\text{End}(\mathcal{D})$ , or equivalently, a monoid  $M$  internal to the category  $\text{End}(\mathcal{D})^{\text{op}}$ .

$$LRLR \xleftarrow{L\eta R} LR \xrightarrow{\epsilon} \text{id}_{\mathcal{D}}$$

## 6 Basic applications

The category  $\bar{\Delta}$  is the free monoidal category on a monoid; that is, whenever we are given a monoidal category  $\mathcal{C}$  and a monoid  $M \in \mathcal{C}$ , it extends to a monoidal functor  $\tilde{M}: \bar{\Delta} \rightarrow \mathcal{C}$ .

$$\begin{array}{ccc} \{*\} & \xrightarrow{[0]} & \bar{\Delta} \\ & \searrow M & \downarrow \exists! \tilde{M} \\ & & \mathcal{C} \end{array}$$

In particular, with  $\mathcal{C} = \text{End}(\mathcal{D})^{\text{op}}$ , the monoid  $LR$  extends to a monoidal functor  $\bar{\Delta} \rightarrow \text{End}(\mathcal{D})^{\text{op}}$ .

$$\begin{array}{ccc} \{*\} & \xrightarrow{[0]} & \bar{\Delta} \\ & \searrow M & \downarrow \exists! \\ & & \text{End}(\mathcal{D})^{\text{op}} \end{array}$$

Equivalently, this gives a functor

$$B: \bar{\Delta}^{\text{op}} \rightarrow \text{End}(\mathcal{D}).$$

For each  $d \in \mathcal{D}$ , there is an evaluation map

$$\text{ev}_d: \text{End}(\mathcal{D}) \rightarrow \mathcal{D}.$$

Composing this with the above functor gives, for each object  $d \in \mathcal{D}$ , a simplicial object in  $\mathcal{D}$ .

$$\bar{\Delta}^{\text{op}} \xrightarrow{B} \text{End}(\mathcal{D}) \xrightarrow{\text{ev}_d} \mathcal{D}$$

**Definition 97** (bar construction). The composition  $\text{ev}_d \circ B$  is called the bar construction.

In the case that the category  $\mathcal{D}$  is abelian, we can form the chain complex associated to a simplicial object. This is known as the the bar complex.

**Example 98.** Consider the functor

$$U: \mathbb{Z}G\text{-Mod} \rightarrow \mathbf{Ab}$$

which forgets multiplication. This has left adjoint

$$\mathbb{Z}G \otimes -: \mathbf{Ab} \rightarrow \mathbb{Z}G\text{-Mod},$$

which

### 6.3.3 Group cohomology

One would like to be able to apply the techniques of homological algebra to the study of groups. Unfortunately, the category **Grp** is not very nicely behaved. Out of any group  $G$ , one can form the group ring  $\mathbb{Z}G$ . This is a minor improvement, but the category **Ring** is also not abelian. In order to study groups using homological techniques, it will therefore be profitable to work instead with modules over the group ring  $\mathbb{Z}G$ ; as a category of modules, it is abelian.

Given a group  $G$ , a  $G$ -module is a functor  $\mathbf{BG} \rightarrow \mathbf{Ab}$ . More generally, the category of such  $G$ -modules is the category  $\mathbf{Fun}(\mathbf{BG}, \mathbf{Ab})$ . We will denote this category by  $G\text{-}\mathbf{Mod}$ .

More explicitly, a  $G$ -module consists of an abelian group  $M$ , and a left  $G$ -action on  $M$ . However, since we are in  $\mathbf{Ab}$ , we have more structure immediately available to us: we can define for  $n \in \mathbb{Z}$ ,  $g \in G$  and  $a \in M$ ,

$$(ng)a = n(ga),$$

and, extending by linearity, a  $\mathbb{Z}G$ -module structure on  $M$ .

Because of the equivalence  $G\text{-}\mathbf{Mod} \simeq \mathbb{Z}G\text{-}\mathbf{Mod}$ , we know that  $G\text{-}\mathbf{Mod}$  has enough projectives.

Note that there is a canonical functor  $\text{triv}: \mathbf{Ab} \rightarrow \mathbf{Fun}(\mathbf{BG}, \mathbf{Ab})$  which takes an abelian group to the associated constant functor.

**Proposition 99.** The functor  $\text{triv}$  has left adjoint

$$(-)_G: M \mapsto M_G = M / \langle g \cdot m - m \mid g \in G, m \in M \rangle$$

and right adjoint

$$(-)^G: M \mapsto M^G = \{m \in M \mid g \cdot m = m\}.$$

That is, there is an adjoint triple

$$(-)_G \longleftrightarrow \text{triv} \longleftrightarrow (-)^G$$

*Proof.* In each case, we exhibit a hom-set adjunction. In the first case, we need a natural isomorphism

$$\text{Hom}_{\mathbf{Ab}}(M_G, A) \equiv \text{Hom}_{G\text{-}\mathbf{Mod}}(M, \text{triv } A).$$

Starting on the left with a homomorphism  $\alpha: M_G \rightarrow A$ , the universal property for quotients allows us to replace it by a homomorphism  $\hat{\alpha}: M \rightarrow A$  such that  $\hat{\alpha}(g \cdot m - m) = 0$  for all  $m \in M$  and  $g \in G$ ; that is to say, a homomorphism  $\hat{\alpha}: M \rightarrow A$  such that

$$\hat{\alpha}(g \cdot m) = \hat{\alpha}(m). \tag{6.2}$$

However, in this form it is clear that we may view  $\hat{\alpha}$  as a  $G$ -linear map  $M \rightarrow \text{triv } A$ .

In fact,  $G$ -linear maps  $M \rightarrow \text{triv } A$  are precisely those satisfying Equation 6.2, showing that this is really an isomorphism.

The other case is similar.  $\square$

**Definition 100** (invariants, coinvariants). For a  $G$ -module  $M$ , we call  $M^G$  the invariants of  $M$  and  $M_G$  the coinvariants.

Note that we actually have a fairly good handle on invariants and coinvariants.

**Lemma 101.** We have the formulae

$$(-)^G \simeq \text{Hom}_{\mathbb{Z}G\text{-Mod}}(\mathbb{Z}, -)$$

and

$$(-)_G \simeq \mathbb{Z} \otimes_{\mathbb{Z}G} -.$$

*Proof.* A  $\mathbb{Z}G$ -linear map  $\mathbb{Z} \rightarrow M$  picks out an element of  $M$  on which  $G$  acts trivially.

Consider the element

$$1 \otimes (m - g \cdot m) \in \mathbb{Z} \otimes_{\mathbb{Z}G} M.$$

By  $\mathbb{Z}G$ -linearity, this is equal to  $1 \otimes m - 1 \otimes m = 0$ .  $\square$

This tells us immediately that the invariants functor  $(-)^G$  is left exact, and the coinvariant functor  $(-)_G$  is right. We could have discovered this by explicit investigation, and formed the right and left derived hom functors. However, this would have required picking resolutions for each object under consideration, which would have been messy. By the balancedness of Tor and Ext, we can simply pick a resolution of  $\mathbb{Z}$  as a  $\mathbb{Z}G$ -module and get on with our lives.<sup>2</sup>

**Example 102.** Let  $T \cong \mathbb{Z}$  be an infinite cyclic group with a single generator  $t$ . Then

$$\mathbb{Z}T \cong \mathbb{Z}[t, t^{-1}],$$

and we have an exact sequence

$$0 \longrightarrow \mathbb{Z}T \xrightarrow{t-1} \mathbb{Z}T \longrightarrow \mathbb{Z} \longrightarrow 0$$

giving a free resolution of  $\mathbb{Z}$  as a  $\mathbb{Z}T$ -module.

In general, our life is not so easy. Fortunately, we still have, for any group  $G$ , a general construction of a free resolution of  $\mathbb{Z}$  as a left  $\mathbb{Z}G$ -module, known as the *bar construction*.

---

<sup>2</sup>In the case of invariants (which correspond to Ext), we need to pick a resolution of  $\mathbb{Z}$  as a *left*  $\mathbb{Z}G$ -module, and in the case of coinvariants (corresponding to Tor), we need to pick a resolution of  $\mathbb{Z}$  as a *right*  $\mathbb{Z}G$ -module.

**Definition 103** (bar complex). Let  $G$  be a group. The bar complex of  $G$  is the chain complex defined level-wise to be the free  $\mathbb{Z}G$ -module

$$B_n = \bigoplus_{(g_i) \in (G \setminus \{e\})^n} \mathbb{Z}G[g_1 | \cdots | g_n],$$

where  $[g_1 | \cdots | g_n]$  is simply a symbol denoting to the basis element corresponding to  $(g_1, \dots, g_n)$ . The differential is defined by

$$d([g_1 | \cdots | g_n]) = g_1[g_2 | \cdots | g_n] + \sum_{i=1}^{n-1} (-1)^i [g_1 | \cdots | g_i g_{i+1} | \cdots | g_n] + (-1)^n [g_1 | \cdots | g_{n-1}].$$

This is in fact a chain complex; the verification of this is identical to the verification of the simplicial identities. First, we note that we can write

$$d_n = d_0 + \sum_{i=1}^{n-1} (-1)^i d_i + (-1)^n d_n,$$

where the  $d_i$  satisfy the simplicial identities

$$d_i d_j = d_{j-1} d_i, \quad i < j.$$

Thus, we have

$$\begin{aligned} d_n \circ d_{n-1} &= \left( \sum_{j=0}^{n-1} (-1)^j d^j \right) \circ \left( \sum_{i=0}^n (-1)^i d^i \right) \\ &= \sum \sum (-1)^{i+j} d^j \circ d^i \\ &= \sum_{0 \leq j < i \leq n} (-1)^{i+j} d^j \circ d^i + \sum_{0 \leq i \leq j \leq n-1} (-1)^{i+j} d^j \circ d^i \\ &= \sum_{0 \leq j < i \leq n} (-1)^{i+j} d^{i-1} \circ d^j + \sum_{0 \leq i \leq j \leq n-1} (-1)^{i+j} d^j \circ d^i \\ &= 0. \end{aligned}$$

**Proposition 104.** For any group  $G$ , the bar construction gives a free resolution of  $\mathbb{Z}$  as a (left)  $\mathbb{Z}G$ -module.

*Proof.* We need to show that the sequence

$$\cdots \longrightarrow B_2 \longrightarrow B_1 \longrightarrow B_0 \xrightarrow{\epsilon} \mathbb{Z} \longrightarrow 0$$

is exact, where  $\epsilon$  is the augmentation map.

We do this by considering the above as a sequence of  $\mathbb{Z}$ -modules, and providing a  $\mathbb{Z}$ -

and in the other

$$\begin{array}{ccc}
 & & g[g_1 | \cdots | g_n] \\
 & \nearrow & \\
 [g|g_1 | \cdots | g_n] & \longmapsto & - \sum_{i=1}^{n-1} [gg_1 | \cdots | g_i g_{i+1} | \cdots | g_n] \\
 & & - (-1)^n [gg_1 | \cdots | g_{n-1}]
 \end{array} \cdot$$

The sum of these is simply  $g[g_1 | \cdots | g_n]$ , i.e. we have

$$h \circ d + d \circ h = \text{id}.$$

This proves exactness as desired.  $\square$

Note that we immediately get a free resolution of  $\mathbb{Z}G$  as a *right*  $\mathbb{Z}G$  by mirroring the construction above.

Thus, we have the following general formulae:

$$H^i(G, A) = H^i \left( 0 \longrightarrow \text{Hom}_{\mathbb{Z}G}(B_0, A) \xrightarrow{(d_1)^*} \text{Hom}_{\mathbb{Z}G}(B_1, A) \xrightarrow{(d_2)^*} \cdots \right)$$

and

$$H_i(G, A) = H_i \left( \cdots \longrightarrow B_1 \otimes_{\mathbb{Z}G} A \longrightarrow B_0 \otimes_{\mathbb{Z}G} A \longrightarrow 0 \right)$$

The story so far is as follows.

1. We fixed a group  $G$  and considered the category  $G\text{-}\mathbf{Mod}$  of functors  $\mathbf{BG} \rightarrow \mathbf{Ab}$ .
2. We noticed that picking out the constant functor gave us a canonical functor  $\mathbf{Ab} \rightarrow G\text{-}\mathbf{Mod}$ , and that taking left- and right adjoints to this gave us interesting things.
  - The right adjoint  $(-)^G$  applied to a  $G$ -module  $A$  gave us the subgroup of  $A$  stabilized by  $G$ .
  - The left adjoint  $(-)_G$  applied to a  $G$ -module  $A$  gave us the  $A$  modulo the stabilized subgroup.
3. Due to adjointness, these functors have interesting exactness properties, leading us to derive them.
  - Since  $(-)_G$  is left adjoint, it is right exact, and we can take the left derived functors  $L_i(-)_G$ .
  - Since  $(-)^G$  is right adjoint, it is left exact, and we can take the right derived

## 6 Basic applications

functors  $R^i(-)^G$ .

4. We denote

$$L_i(-)_G = H_i(G, -), \quad R^i(-)^G = H^i(G, -),$$

and call them *group homology* and *group cohomology* respectively.

5. We notice that, taking  $\mathbb{Z}$  as a trivial  $\mathbb{Z}G$ -module, we have

$$A_G \equiv \mathbb{Z} \otimes_{\mathbb{Z}G} A, \quad A^G \equiv \text{Hom}_{\mathbb{Z}G}(\mathbb{Z}, A),$$

and thus that

$$H_i(G, A) = \text{Tor}_i^{\mathbb{Z}G}(\mathbb{Z}, A), \quad H^i(G, A) = \text{Ext}_{\mathbb{Z}G}^i(\mathbb{Z}, A).$$

This means that (by balancedness of Tor and Ext) we can compute group homology and cohomology by taking a resolution of  $\mathbb{Z}$  as a free  $\mathbb{Z}G$ -module, rather than having to take resolutions of  $A$  for all  $A$ . The bar complex gave us such a resolution.

**Example 105.** Let  $G$  be a group, and consider  $\mathbb{Z}$  as a free  $\mathbb{Z}G$ -module. Let us compute  $H_1(G, \mathbb{Z})$  and  $H^1(G, \mathbb{Z})$ .

To compute  $H_1(G, \mathbb{Z})$ , consider the sequence

$$\begin{array}{ccccccc} \cdots & \xrightarrow{d_2 \otimes \text{id}_{\mathbb{Z}}} & \bigoplus_{g \in G \setminus \{1\}} [g] \mathbb{Z}G \otimes_{\mathbb{Z}G} \mathbb{Z} & \xrightarrow{d_1 \otimes \text{id}_{\mathbb{Z}}} & [\cdot] \mathbb{Z}G \otimes_{\mathbb{Z}G} \mathbb{Z} & \longrightarrow & 0 \\ & & \parallel & & \parallel & & \\ \cdots & \longrightarrow & \bigoplus [g] \mathbb{Z} & \longrightarrow & [\cdot] \mathbb{Z} & \longrightarrow & 0 \end{array}$$

The differential  $d_1 \otimes \text{id}_{\mathbb{Z}}$  acts on  $[g]$  by sending it to

$$[\cdot]g - [\cdot] = [\cdot] - [\cdot],$$

i.e. everything is a cycle. The differential  $d_2$  sends

$$[g|h] \mapsto [g]h - [gh] + [h] = [g] + [h] - [gh],$$

i.e. the terms  $[gh]$  and  $[g] + [h]$  are identified. Thus,  $H_1(G, \mathbb{Z})$  is simply the abelianization of  $G$ .

To compute  $H^1(G, \mathbb{Z})$ , consider the sequence

$$0 \longrightarrow \text{Hom}_{\mathbb{Z}G}(\mathbb{Z}G[\cdot], \mathbb{Z}) \xrightarrow{(d_1)^*} \text{Hom}_{\mathbb{Z}G}(\bigoplus_{g \in G \setminus \{1\}} \mathbb{Z}G[g], \mathbb{Z}) \xrightarrow{(d_2)^*} \cdots$$

Notice immediately that since the hom functor preserves direct sums in the first slot,

we have

$$\begin{aligned} \operatorname{Hom}_{\mathbb{Z}G} \left( \bigoplus_{(g_i) \in (G \setminus \{1\})^n} \mathbb{Z}G[g_1 | \cdots | g_n], \mathbb{Z} \right) &\cong \bigoplus_{(g_i) \in (G \setminus \{1\})^n} \operatorname{Hom}_{\mathbb{Z}G} (\mathbb{Z}G[g_1 | \cdots | g_n], \mathbb{Z}) \\ &\cong \bigoplus_{(g_i) \in (G \setminus \{1\})^n} \mathbb{Z}[g_1 | \cdots | g_n]. \end{aligned}$$

This notation deserves some explanation; recall that the symbols  $[g_1 | \cdots | g_n]$  are merely visual aids, reminding us where we are and how the differential acts. The differential

$$(d_n)^* : [g_1 | \cdots | g_n].$$

In the low cases we have the sequence

# 7 Spectral sequences

## 7.1 Motivation

Let  $E_{\bullet,\bullet}$  be a first-quadrant double complex. As we saw in [Section 5.7](#), computing the homology of the total complex of such a double complex is in general difficult with no further information, for example exactness of rows or columns. Spectral sequences provide a means of calculating, among other things, the building blocks of the homology of the total complex such a double complex.

They do this via a series of successive approximations. One starts with a first-quadrant double complex  $E_{\bullet,\bullet}$ .

One first forgets the data of the horizontal differentials (or equivalently, sets them to zero). To avoid confusion, one adds a subscript, denoting this new double complex by

$$E^0_{\bullet,\bullet}$$

$$H_q(E_{p,\bullet}^0) = E_{p,q}^1.$$

The functoriality of  $H_q$  means that the maps  $H_q(d^h)$  act as differentials for the rows.

We now write  $E_{p,q}^2$  for the horizontal homology  $H_p(E_{\bullet,q}^1)$ .

The claim is that the terms  $E_{p,q}^r$  are pieces of a successive approximation of the homology of the total complex  $\text{Tot}(E)$ . In the particularly simple case that  $E_{\bullet,\bullet}$  consists of only two nonzero adjacent columns, we have already succeeded in computing the total homology, at least up to an extension problem.

**Proposition 106.** Let  $E$  be a double complex where all but two adjacent columns are zero; that is, let  $E$  be a diagram consisting of two chain complexes and a morphism between them, padded by zeroes on either side.

$$\begin{array}{ccc}
 \vdots & & \vdots \\
 \downarrow & & \downarrow \\
 D_3 & \xleftarrow{f_3} & C_3 \\
 d_3^D \downarrow & & \downarrow -d_3^C \\
 D_2 & \xleftarrow{f_2} & C_2 \\
 d_2^D \downarrow & & \downarrow -d_2^C \\
 D_1 & \xleftarrow{f_1} & C_1 \\
 d_1^D \downarrow & & \downarrow -d_1^C \\
 D_0 & \xleftarrow{f_0} & C_0 \\
 d_0^D \downarrow & & \downarrow -d_0^C \\
 D_{-1} & \xleftarrow{f_{-1}} & C_{-1} \\
 \downarrow & & \downarrow \\
 \vdots & & \vdots
 \end{array}$$

Note that we have multiplied the differentials of  $C$  by  $-1$  so that we have a double complex.

Fix some  $n \in \mathbb{Z}$ , and let  $q = n - p$ .

Let  $T = \text{Tot}(E)$ ; that is, let  $T = \text{Cone}(f)$ . Then we have a short exact sequence

$$0 \longrightarrow E_{p-1,q+1}^2 \hookrightarrow H_{p+q}(T) \twoheadrightarrow E_{p,q}^2 \longrightarrow 0$$

*Proof.* Recall that  $\text{Cone}(f)$  fits into the following short exact sequence,

$$0 \longrightarrow C_{\bullet} \hookrightarrow D_{\bullet} \twoheadrightarrow \text{Cone}(f)_{\bullet} \longrightarrow 0$$

Since by assumption  $d^v b = 0$  we have that

$$d^v \phi^0(a, b) = d^v b = 0,$$

which is to say that  $\text{im } \phi^0 \subset \ker d^v$ , so  $\phi^0$  descends to  $\ker d^v$ , and therefore to a map

$$\phi^1: U \rightarrow E_{p,q}^1; \quad (a, b) \mapsto b + B_{p,q}^1.$$

Since

$$H_q(d^h)(b + B_{p,q}^1) = d^v(-a) + B_{p-1,q}^1 = 0 + B_{p-1,q}^1,$$

we have that  $\text{im } \phi^1 \subset \ker H_q(d^h)$ , so the map  $\phi^1$  descends to  $\ker H_q(d^h)$ , and therefore to a map

$$\phi: U \rightarrow E_{p,q}^2; \quad (a, b) \mapsto (b + B_{p,q}^1) + B_{p,q}^2.$$

Next, we show that  $\phi$  is surjective. Pick some  $\tilde{y} \in E_{p,q}^2$ .

$$\tilde{y} = \underbrace{\left( \overbrace{y}^{\in Z_{p,q}^1} + B_{p,q}^1 \right) + B_{p,q}^2}_{\in Z_{p,q}^2} \in E_{p,q}^2.$$

The fact that  $y \in Z_{p,q}^1$  means that  $d^v y = 0$ . Thus, if we can find some  $x \in E_{p+1,q-1}$  such that

$$d^v x + d^h y = 0,$$

then  $(x, y)$  will lie in  $U$  and  $\phi(x, y) = \tilde{y}$ , so we will be done.

The fact that  $y + B_{p,q}^1 \in Z_{p,q}^2$  means that  $H_q(d^h)(y + B_{p,q}^1) = 0 + B_{p-1,q}^1$ , i.e. that  $d^h y \in B_{p-1,q}^1$ . Thus, there exists  $-x \in E_{p-1,q+1}$  such that

$$d^v(-x) = d^h y.$$

Thus, we have found our  $(x, y) \in U$ , so  $\phi$  is surjective.

We will be done if we can show that  $\ker \phi = V$ .

The following calculations show that  $V \subset \ker \phi$ .

- $\phi(a, 0) = (0 + B_{p,q}^1) + B_{p,q}^2.$
- $\phi(d^h x, d^v x) = (d^v x + B_{p,q}^1) + B_{p,q}^2 = (0 + B_{p,q}^1) + B_{p,q}^2.$
- $\phi(0, d^h c) = (d^h c + B_{p,q}^1) + B_{p,q}^2 = H_q(d^h)(c + B_{p+1,q}^1) + B_{p,q}^2 = [0] + B_{p,q}^2.$

Now, let  $(x, y) \in \ker \phi$ . How in the hell...? □

**Definition 108** (filtration). Let  $C_\bullet$  be a chain complex. A filtration of  $C_\bullet$  is a chain of

## 7 Spectral sequences

monomorphisms of subcomplexes  $F_p C_\bullet \subset$  of  $C_\bullet$ .

$$\cdots \hookrightarrow F_{p-1} C_\bullet \hookrightarrow F_p C_\bullet \hookrightarrow F_{p+1} C_\bullet \hookrightarrow \cdots$$

# 8 Algebraic topology

## 8.1 Basic definitions and examples

We assume a basic knowledge of simplicial sets just to get the ball rolling.

**Definition 109** (singular complex, singular homology). Let  $X$  be a topological space. The singular chain complex  $C_\bullet(X)$  is defined level-wise by

$$C_n(X) = N(\mathcal{F}(\text{Sing}(X)))$$

where  $\mathcal{F}$  denotes the free group functor and  $N$  is the Moore functor ([Definition 92](#)). That is, it has differentials

$$d_n: C_n \rightarrow C_{n-1}; \quad (\alpha: \Delta^n \rightarrow X) \mapsto \sum_{i=0}^n \partial^i \alpha.$$

The singular homology of  $X$  is the homology

$$H_n(X) = H_n(C_\bullet(X)).$$

Note that the singular chain complex construction is functorial: any map  $f: X \rightarrow Y$  gives a chain map  $C(f): C(X) \rightarrow C(Y)$ . This immediately implies that the  $n$ th homology of a space  $X$  is invariant under homeomorphism.

**Example 110.** Denote by  $\text{pt}$  the one-point topological space. Then  $C(\text{pt})_\bullet$  is given level-wise as follows.

$$\begin{array}{ccccccccccccccc} \cdots & \xrightarrow{\text{id}} & \mathbb{Z} & \xrightarrow{0} & \mathbb{Z} & \xrightarrow{\text{id}} & \mathbb{Z} & \xrightarrow{0} & \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \cdots \\ & & \parallel & & \parallel & & \parallel & & \parallel & & \parallel & & \\ \cdots & \xrightarrow{d_4} & C_3 & \xrightarrow{d_3} & C_2 & \xrightarrow{d_2} & C_1 & \xrightarrow{d_1} & C_0 & \xrightarrow{d_0} & C_{-1} & \xrightarrow{d_{-1}} & \cdots \end{array}$$

Thus, the  $n$ th homology of the point is

$$H_n(\text{pt}) = \begin{cases} \mathbb{Z}, & n = 0 \\ 0, & n \neq 0 \end{cases}.$$

**Example 111.** Let  $X$  be a path-connected topological space. Then  $H_0(X) = \mathbb{Z}$ . To see this, consider a general element of  $H_0(X)$ . Because  $d_0$  is the zero map,  $H_n(X)$  is simply the free group generated by the collection of points of  $X$  modulo the relation “there is a path from  $x$  to  $y$ .” However, path-connectedness implies that every two points of  $X$  are connected by a path, so every point of  $X$  is equivalent to any other. Thus,  $H_0(X)$  has only one generator.

More generally,

$$H_n(X) = \mathbb{Z}^{\pi_0(X)}.$$

## 8.2 The Hurewicz homomorphism

**Theorem 112** (Hurewicz). For any path-connected topological space  $X$ , there is an isomorphism

$$h_X: H_1(X) \cong \pi_1(X)_{\text{ab}},$$

where  $(-)_{\text{ab}}$  denotes the abelianization. Furthermore, the maps  $h_X$  form the components of a natural isomorphism between the functors

$$h: H_1 \Rightarrow (\pi_1)_{\text{ab}}.$$

**Example 113.** We can now confidently say that

$$H_1(\mathbb{S}^1) = \pi_1(\mathbb{S}^1)_{\text{ab}} = \mathbb{Z},$$

and that

$$H_1(\mathbb{S}^n) = 0, \quad n > 1.$$

**Example 114.** Since

$$\pi_1(X \times Y) \cong \pi_1(X) \times \pi_1(Y)$$

and

$$\pi_1(X \vee Y) \cong \pi_1(X) * \pi_1(Y),$$

we have that

$$H_1(X \times Y) \cong H_1(X) \times H_1(Y) \cong H_1(X \vee Y).$$

## 8.3 Homotopy equivalence

**Proposition 115.** Let  $f, g: X \rightarrow Y$  be continuous maps between topological spaces, and let  $H: X \times [0, 1] \rightarrow Y$  be a homotopy between them. Then  $H$  induces a homotopy between  $C(f)$  and  $C(g)$ . In particular,  $f$  and  $g$  agree on homology.

**Corollary 116.** Any two topological spaces which are homotopy equivalent have the same homology groups.

**Example 117.** Any contractible space is homotopy equivalent to the one point space pt. Thus, for any contractible space  $X$  we have

$$H_n(X) = \begin{cases} \mathbb{Z}, & n = 0 \\ 0, & n \neq 0 \end{cases}$$

## 8.4 Relative homology; the long exact sequence of a pair of spaces

**Definition 118** (relative homology). Let  $X$  be a topological space, and let  $X \subset A$ . The relative chain complex of  $(X, A)$  is

$$S_\bullet(X, A) = S_\bullet(X)/S_\bullet(A).$$

The relative homology of  $(X, A)$  is

$$H_n(X, A) = H_n(S_\bullet(X, A)).$$

Denote by **Pair** the category whose objects are pairs  $(X, A)$ , where  $X$  is a topological space and  $A \hookrightarrow X$  is a subspace, and whose morphisms  $(X, A) \rightarrow (Y, B)$  are maps  $f: X \rightarrow Y$  such that  $f(A) \subset B$ .

**Lemma 119.** For each  $n$ , relative homology provides a functor  $H_n: \mathbf{Pair} \rightarrow \mathbf{Ab}$ .

*Proof.* Consider the following diagram

$$\begin{array}{ccc} S(X)_\bullet & \xrightarrow{f} & S(Y)_\bullet \\ \downarrow & & \downarrow \\ S(X)_\bullet/S(A)_\bullet & \dashrightarrow & S(Y)_\bullet/S(B)_\bullet \end{array}$$

The dashed arrow is well-defined because of the assumption that  $f(A) \subset B$ . Functoriality now follows from the functoriality of  $H_n$ .  $\square$

**Proposition 120.** Let  $(X, A)$  be a pair of spaces. There is the following long exact se-

quence.

$$\begin{array}{ccccccc}
 & & \cdots & \longrightarrow & H_{j+1}(X, A) & & \\
 & \swarrow & & & \searrow & \delta & \\
 & & H_j(A) & \longrightarrow & H_j(X) & \longrightarrow & H_j(X, A) \\
 & \swarrow & & & \searrow & \delta & \\
 & & H_{j-1}(A) & \longrightarrow & \cdots & & 
 \end{array}$$

*Proof.* This is the long exact sequence associated to the following short exact sequence.

$$0 \longrightarrow C_\bullet(A) \hookrightarrow C_\bullet(X) \twoheadrightarrow C_\bullet(X, A) \longrightarrow 0$$

□

**Example 121.** Let  $X = \mathbb{D}^n$ , the  $n$ -disk, and  $A = \mathbb{S}^{n-1}$  its boundary  $n$ -sphere.

Consider the long exact sequence on the pair  $(\mathbb{D}^n, \mathbb{S}^{n-1})$ .

$$\begin{array}{ccccccc}
 & & \cdots & \longrightarrow & H_{j+1}(\mathbb{D}^n, \mathbb{S}^{n-1}) & & \\
 & \swarrow & & & \searrow & \delta & \\
 & & H_j(\mathbb{S}^{n-1}) & \longrightarrow & H_j(\mathbb{D}^n) & \longrightarrow & H_j(\mathbb{D}^n, \mathbb{S}^{n-1}) \\
 & \swarrow & & & \searrow & \delta & \\
 & & H_{j-1}(\mathbb{S}^{n-1}) & \longrightarrow & \cdots & & 
 \end{array}$$

We know that  $H_j(\mathbb{D}^n) = 0$  for  $n > 0$  because it is contractible.

Thus, exactness forces

$$H_j(\mathbb{D}^n, \mathbb{S}^{n-1}) \cong H_{j-1}(\mathbb{S}^{n-1})$$

for  $j > 1$  and  $n \geq 1$ .

## 8.5 Barycentric subdivision

**Fact 122.** Let  $X$  be a topological space, and let  $\mathcal{U} = \{U_i \mid i \in I\}$  be an open cover of  $X$ . Denote by

$$S_n^{\mathcal{U}}(X)$$

the free group generated by those continuous functions

$$\alpha: \Delta^n \rightarrow X$$

whose images are completely contained in some open set in the open cover  $\mathcal{U}$ . That is, such that there exists some  $i$  such that  $\alpha(\Delta^n) \subset U_i$ . The inclusion  $S_n^{\mathcal{U}}(X) \hookrightarrow S_n(X)$

induces a cochain structure on  $S_\bullet^{\mathfrak{U}}(X)$ .

$$\begin{array}{ccccccc} \cdots & \longrightarrow & S_2^{\mathfrak{U}}(X) & \longrightarrow & S_1^{\mathfrak{U}}(X) & \longrightarrow & S_0^{\mathfrak{U}}(X) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \longrightarrow & S_2(X) & \longrightarrow & S_1(X) & \longrightarrow & S_0(X) \longrightarrow 0 \end{array}$$

In fact, this inclusion is homotopic to the identity, hence induces an isomorphism

$$H_n^{\mathfrak{U}}(X) := H_n(S^{\mathfrak{U}}(X)_\bullet) \cong H_n(X).$$

This fact allows us almost immediately to read off two important theorems.

### 8.5.1 Excision

**Theorem 123** (excision). Let  $W \subset A \subset X$  be a triple of topological spaces such that  $\bar{W} \subset \mathring{A}$ . Then the right-facing inclusions

$$\begin{array}{ccc} A \setminus W & \xhookrightarrow{i} & A \\ \downarrow & & \downarrow \\ X \setminus W & \xhookrightarrow{i} & X \end{array}$$

induce an isomorphism

$$H_n(i): H_n(X \setminus W, A \setminus W) \cong H_n(X, A).$$

That is, when considering relative homology  $H_n(X, A)$ , we may cut away a subspace from the interior of  $A$  without harming anything. This gives us a hint as to the interpretation of relative homology:  $H_n(X, A)$  can be interpreted the part of  $H_n(X)$  which does not come from  $A$ .

### 8.5.2 The Mayer-Vietoris sequence

**Theorem 124** (Mayer-Vietoris). Let  $X$  be a topological space, and let  $\mathcal{U} = \{X_1, X_2\}$  be an open cover of  $X$ , i.e. let  $X = X_1 \cup X_2$ . Then we have the following long exact sequence.

$$\begin{array}{ccccccc}
 & & & & \dots & \longrightarrow & H_{n+1}(X) \\
 & & & & & & \uparrow \delta \\
 & & & & H_n(X_1 \cap X_2) & \longrightarrow & H_n(X_1) \oplus H_n(X_2) \longrightarrow H_n(X) \\
 & & & & & & \uparrow \delta \\
 & & & & H_{n-1}(X_1 \cap X_2) & \longrightarrow & \dots
 \end{array}$$

*Proof.* We can draw our inclusions as the following pushout.

$$\begin{array}{ccccc}
 & & X_1 & & \\
 & \nearrow i_1 & & \searrow \kappa_1 & \\
 X_1 \cap X_2 & & & & X \\
 & \searrow i_2 & & \nearrow \kappa_2 & \\
 & & X_2 & & 
 \end{array}$$

We have, almost by definition, the following short exact sequence.

$$0 \longrightarrow S_\bullet(X_1 \cap X_2) \xrightarrow{(i_1, i_2)} S_\bullet(X_1) \oplus S_\bullet(X_2) \xrightarrow{\kappa_1 - \kappa_2} S_\bullet^{\mathcal{U}}(X) \longrightarrow 0$$

This gives the following long exact sequence on homology.

$$\begin{array}{ccccccc}
 & & & & \dots & \longrightarrow & H_{n+1}^{\mathcal{U}}(X) \\
 & & & & & & \uparrow \delta \\
 & & & & H_n(X_1 \cap X_2) & \longrightarrow & H_n(X_1) \oplus H_n(X_2) \longrightarrow H_n^{\mathcal{U}}(X) \\
 & & & & & & \uparrow \delta \\
 & & & & H_{n-1}(X_1 \cap X_2) & \longrightarrow & \dots
 \end{array}$$

We have seen that  $H^{\mathcal{U}}(n)(X) \cong H_n(X)$ ; the result follows.  $\square$

**Example 125** (Homology groups of spheres). We can decompose  $\mathbb{S}^n$  as

$$\mathbb{S}^n = (\mathbb{S}^n \setminus N) \cup (\mathbb{S}^n \setminus S),$$

where  $N$  and  $S$  are the North and South pole respectively. This gives us the following

pushout.

$$\begin{array}{ccccc}
 & & \mathbb{S}^n \setminus N & & \\
 & \nearrow & & \searrow & \\
 (\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S) & & & & \mathbb{S}^n \\
 & \searrow & & \nearrow & \\
 & & \mathbb{S}^n \setminus S & &
 \end{array}$$

The Mayer-Vietoris sequence is as follows.

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{j+1}(\mathbb{S}^n) \\
 & & & & \searrow & \delta & \nearrow \\
 & & H_j((\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S)) & \longrightarrow & H_j(\mathbb{S}^n \setminus N) \oplus H_j(\mathbb{S}^n \setminus S) & \longrightarrow & H_j^{\text{all}}(X) \\
 & & \searrow & \delta & \nearrow \\
 & & H_{j-1}((\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S)) & \longrightarrow & \cdots & &
 \end{array}$$

We know that

$$\mathbb{S}^n \setminus N \cong \mathbb{S}^n \setminus S \cong \mathbb{D}^n \simeq \text{pt}$$

and that

$$(\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S) \cong I \times \mathbb{S}^{n-1} \simeq \mathbb{S}^{n-1},$$

so using the fact that homology respects homotopy, the above exact sequence reduces (for  $j > 1$ ) to

$$\begin{array}{ccccccc}
 & & \cdots & \longrightarrow & H_{j+1}(\mathbb{S}^n) & & \\
 & & \searrow & \delta & \nearrow & & \\
 & & H_j(\mathbb{S}^{n-1}) & \longrightarrow & 0 & \longrightarrow & H_j(\mathbb{S}^n) \\
 & & \searrow & \delta & \nearrow & & \\
 & & H_{j-1}(\mathbb{S}^{n-1}) & \longrightarrow & \cdots & &
 \end{array}$$

Thus, for  $i > 1$ , we have

$$H_i(\mathbb{S}^j) \cong H_{i-1}(\mathbb{S}^{j-1}).$$

We have already noted the following facts.

- $H_0$  counts the number of connected components, so

$$H_0(\mathbb{S}^j) = \begin{cases} \mathbb{Z} \oplus \mathbb{Z}, & j = 0 \\ \mathbb{Z}, & j > 0 \end{cases}$$

## 8 Algebraic topology

- For path connected  $X$ ,  $H_1(X) \cong \pi_1(X)_{\text{ab}}$ , so

$$H_1(\mathbb{S}^j) = \begin{cases} \mathbb{Z}, & j = 0 \\ 0, & \text{otherwise} \end{cases}$$

- For  $i > 0$ ,  $H_i(\text{pt}) = 0$ , so  $H_i(\mathbb{S}^0) = 0$ .

This gives us the following table.

$j = 3$	$\mathbb{Z}$	0		
$j = 2$	$\mathbb{Z}$	0		
$j = 1$	$\mathbb{Z}$	$\mathbb{Z}$		
$j = 0$	$\mathbb{Z} \oplus \mathbb{Z}$	0	0	0
$H_i(\mathbb{S}^j)$	$i = 0$	$i = 1$	$i = 2$	$i = 3$

The relation

$$H_i(\mathbb{S}^j) \cong H_{i-1}(\mathbb{S}^{j-1}), \quad i > 1$$

allows us to fill in the above table as follows.

$j = 3$	$\mathbb{Z}$	0	0	$\mathbb{Z}$
$j = 2$	$\mathbb{Z}$	0	$\mathbb{Z}$	0
$j = 1$	$\mathbb{Z}$	$\mathbb{Z}$	0	0
$j = 0$	$\mathbb{Z} \oplus \mathbb{Z}$	0	0	0
$H_i(\mathbb{S}^j)$	$i = 0$	$i = 1$	$i = 2$	$i = 3$

(8.1)

**Example 126.** Above, we used the Hurewicz homomorphism to see that

$$H_1(\mathbb{S}^j) = \begin{cases} \mathbb{Z}, & j = 1 \\ 0, & \text{otherwise} \end{cases}.$$

We can also see this directly from the Mayer-Vietoris sequence. Recall that we expressed  $\mathbb{S}^n$  as the following pushout, with  $X^+ \cong X^- \simeq \mathbb{D}^n$ .

$$\begin{array}{ccc} & X^+ & \\ \nearrow & & \searrow \\ X^+ \cap X^- & & \mathbb{S}^n \\ \searrow & & \nearrow \\ & X^- & \end{array}$$

Also recall that with this setup, we had  $X^+ \cap X^- \simeq \mathbb{S}^{n-1}$ .

First, fix  $n > 1$ , and consider the following part of the Mayer-Vietoris sequence.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & 0 & \longrightarrow & H_1(\mathbb{S}^n) & & \\ & & & & \searrow \delta & \nearrow & \\ & H_0(X^+ \cap X^-) & \xrightarrow{H_0(i_0, i_1)} & H_0(X^+) \oplus H_0(X^-) & \longrightarrow & \cdots & \end{array}$$

If we can verify that the morphism  $H_0(i_0, i_1)$  is injective, then we are done, because exactness will force  $H_1(\mathbb{S}^n) \cong 0$ .

The elements of  $H_0(X^+ \cap X^-)$  are equivalence classes of points of  $X^+$  and  $X^-$ , with one equivalence class per connected component. Let  $p \in X^+ \cap X^-$ . Then  $i_0(p)$  is a point of  $X^+$ , and  $i_1(p)$  is a point of  $X^-$ . Each of these is a generator for the corresponding zeroth homology, so  $(i_0, i_1)$  sends the generator  $[p]$  to the pair  $([i_0(p)], [i_1(p)])$ . This is clearly injective.

Now let  $n = 1$ , and consider the following portion of the Mayer-Vietoris sequence.

$$\begin{array}{ccccccc} \dots & \longrightarrow & 0 & \longrightarrow & H_1(\mathbb{S}^1) \\ & & & \searrow \scriptstyle{\delta} & \\ & & & & H_0(X^+ \cap X^-) \xrightarrow{H_0(i_0, i_1)} H_0(X^+) \oplus H_0(X^-) \xrightarrow{H_0(\kappa_1) - H_0(\kappa_2)} H_0(\mathbb{S}^1) \end{array}$$

We can immediately replace things we know, finding the following.

$$(a, b) \longmapsto (a + b, a + b)$$

$$0 \longrightarrow H_1(\mathbb{S}^1) \hookrightarrow \mathbb{Z} \oplus \mathbb{Z} \xrightarrow{f} \mathbb{Z} \oplus \mathbb{Z} \longrightarrow \mathbb{Z}$$

$$(c, d) \mapsto c - d$$

The kernel of  $f$  is the free group generated by  $(a, a)$ . Thus,  $H_1(\mathbb{S}^1) \cong \mathbb{Z}$ .

### 8.5.3 The relative Mayer-Vietoris sequence

**Theorem 127** (relative Mayer-Vietoris sequence). Let  $X$  be a topological space, and let  $A, B \subset X$  open in  $A \cup B$ . Denote  $\mathfrak{U} = \{A, B\}$ .

## 8 Algebraic topology

Then there is a long exact sequence

$$\begin{array}{ccccccc}
 & & & & \cdots & \longrightarrow & H_{n+1}(X, A \cup B) \\
 & \swarrow & & & \delta & \searrow & \\
 & H_n(X, A \cap B) & \longrightarrow & H_n(X, A) \oplus H_n(X, B) & \longrightarrow & H_n(X, A \cup B) & \\
 & \swarrow & & & \delta & \searrow & \\
 & H_{n-1}(X, A \cap B) & \longrightarrow & \cdots & & & 
 \end{array}$$

*Proof.* Consider the following chain complex of chain complexes.

$$\begin{array}{ccccccc}
 & 0 & & 0 & & 0 & \\
 & \downarrow & & \downarrow & & \downarrow & \\
 0 & \longrightarrow & S_n(A \cap B) & \longrightarrow & S_n(A) \oplus S_n(B) & \longrightarrow & S_n^{\mathcal{U}}(A \cup B) \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & S_n(X) & \longrightarrow & S_n(X) \oplus S_n(X) & \longrightarrow & S_n(X) \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 0 & \longrightarrow & S_n(X, A \cap B) & \longrightarrow & S_n(X, A) \oplus S_n(X, B) & \longrightarrow & S_n(X)/S_n^{\mathcal{U}}(A \cup B) \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow \\
 & & 0 & & 0 & & 0
 \end{array}$$

All columns are trivially short exact sequences, as are the first two rows. Thus, the nine lemma ([Theorem 41](#)) implies that the last row is also exact.

Consider the following map of chain complexes; the first row is the last column of the above grid.

$$\begin{array}{ccccccc}
 0 & \longrightarrow & S_n^{\mathcal{U}}(A \cup B) & \hookrightarrow & S_n(X) & \twoheadrightarrow & S_n(X)/S_n^{\mathcal{U}}(A \cup B) \longrightarrow 0 \\
 & & \phi \downarrow & & \parallel & & \downarrow \psi \\
 0 & \longrightarrow & S_n(A \cup B) & \longrightarrow & S_n(X) & \twoheadrightarrow & S_n(X, A \cup B) \longrightarrow 0
 \end{array}$$

This gives us, by [Lemma 38](#), a morphism of long exact sequences on homology.

$$\begin{array}{ccccccc}
 H_n(S_{\bullet}^{\mathcal{U}}(A \cup B)) & \longrightarrow & H_n(X) & \longrightarrow & H_n(S_{\bullet}(X)/S_{\bullet}^{\mathcal{U}}(A \cup B)) & \longrightarrow & H_{n-1}(S_{\bullet}^{\mathcal{U}}(A \cup B)) \longrightarrow H_{n-1}(X) \\
 H_n(\phi) \downarrow & & \parallel & & \downarrow H_n(\psi) & & \downarrow H_{n-1}(\phi) & \parallel \\
 H_n(A \cup B) & \longrightarrow & H_n(X) & \longrightarrow & H_n(X, A \cup B) & \longrightarrow & H_{n-1}(A \cup B) & \longrightarrow H_{n-1}(X)
 \end{array}$$

We have seen (in [Fact 122](#)) that  $H_i(\phi)$  is an isomorphism for all  $i$ . Thus, the five lemma ([Theorem 40](#)) tells us that  $H_n(\psi)$  is an isomorphism.  $\square$

## 8.6 Reduced homology

It would be hard to argue that Table 8.1 is not pretty, but it would be much prettier were it not for the  $\mathbb{Z}$ s in the first column. We have to carry these around because every non-empty space has at least one connected component.

The solution is to define a new homology  $\tilde{H}_n(X)$  which agrees with  $H_n(X)$  in positive degrees, and is missing a copy of  $\mathbb{Z}$  in the zeroth degree. There are three equivalent ways of doing this: one geometric, one algebraic, and one somewhere in between.

1. **Geometric:** Denoting the unique map  $X \rightarrow \text{pt}$  by  $\epsilon$ , one can define relative homology by

$$\tilde{H}_n(X) = \ker H_n(\epsilon).$$

2. **In between:** One can replace homology  $H_n(X)$  by relative homology

$$\tilde{H}_n(X) = H_n(X, x),$$

where  $x \in X$  is any point of  $x$ .

3. **Algebraic:** One can augment the singular chain complex  $C_\bullet(X)$  by adding a copy of  $\mathbb{Z}$  in degree  $-1$ , so that

$$\tilde{C}_n(X) = \begin{cases} C_n(X), & n \neq -1 \\ \mathbb{Z}, & n = -1. \end{cases}$$

Then one can define

$$\tilde{H}_n(X) = H_n(\tilde{C}_\bullet).$$

There is a more modern point of view, which is the following. In constructing the singular chain complex of our space  $X$ , we used the following composition.

$$\mathbf{Top} \xrightarrow{\text{Sing}} \mathbf{Set}_\Delta \xrightarrow{\mathcal{F}} \mathbf{Ab}_\Delta \xrightarrow{N} \mathbf{Ch}(\mathbf{Ab})$$

For many purposes, there is a more natural category than  $\Delta$  to use: the category  $\bar{\Delta}$ , which includes the empty simplex  $[-1]$ . The functor **Sing** now has a component corresponding to  $(-1)$ -simplices:

$$\mathbf{Sing}(X)_{-1} = \text{Hom}_{\mathbf{Top}}(\rho([-1]), X) = \text{Hom}_{\mathbf{Top}}(\emptyset, X) = \{*\},$$

since the empty topological space is initial in **Top**. Passing through  $\mathcal{F}$  thus gives a copy of  $\mathbb{Z}$  as required. Thus, using  $\bar{\Delta}$  instead of  $\Delta$  gives the augmented singular chain complex.

These all have the desired effect, and which method one uses is a matter of preference. To see this, note the following.

- (1  $\Leftrightarrow$  2): Since the composition

$$\text{pt} \xrightarrow{x} X \xrightarrow{\epsilon} \text{pt}$$

is a weak retract, the sequence

$$0 \longrightarrow S_n(\text{pt}) \longrightarrow S_n(X) \longrightarrow S_n(X, \{x\}) \longrightarrow 0$$

**Proposition 128.** Relative homology agrees with ordinary homology in degrees greater than 0, and in degree zero we have the relation

$$H_0(X) = \tilde{H}_0(X) \oplus \mathbb{Z}.$$

*Proof.* Trivial from algebraic definition. □

Many of our results for regular homology hold also for reduced homology.

**Proposition 129.** There is a long exact sequence for a pair of spaces

$$\begin{array}{ccccccc} & & \cdots & \longrightarrow & \tilde{H}_{j+1}(X, A) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ \tilde{H}_j(A) & \longrightarrow & \tilde{H}_j(X) & \longrightarrow & \tilde{H}_j(X, A) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ \tilde{H}_{j-1}(A) & \longrightarrow & \cdots & & & & \end{array}$$

**Proposition 130.** We have a reduced Mayer-Vietoris sequence.

$$\begin{array}{ccccccc} & & \cdots & \longrightarrow & \tilde{H}_{n+1}(X) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ \tilde{H}_n(X_1 \cap X_2) & \longrightarrow & \tilde{H}_n(X_1) \oplus \tilde{H}_n(X_2) & \longrightarrow & \tilde{H}_n(X) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ \tilde{H}_{n-1}(X_1 \cap X_2) & \longrightarrow & \cdots & & & & \end{array}$$

**Proposition 131.** Let  $\{(X_i, x_i)\}_{i \in I}$  be a set of pointed topological spaces such that each  $x_i$  has an open neighborhood  $U_i \subset X_i$  of which it is a deformation retract. Then for any finite  $E \subset I$ <sup>1</sup> we have

$$\tilde{H}_n \left( \bigvee_{i \in I} X_i \right) \cong \bigoplus_{i \in E} \tilde{H}_n(X_i).$$

<sup>1</sup>This finiteness condition is not actually necessary, but giving it here avoids a colimit argument.

*Proof.* We prove the case of two bouquet summands; the rest follows by induction. We know that

$$X_1 \vee X_2 = (X_1 \vee U_2) \cup (U_1 \vee X_2)$$

is an open cover. Thus, the reduced Mayer-Vietoris sequence of [Proposition 130](#) tells us that the following sequence is exact.

$$0 \longrightarrow \tilde{H}_n(X_1) \oplus \tilde{H}_n(X_2) \longrightarrow \tilde{H}_n(X) \longrightarrow 0$$

In particular, for  $n > 0$ , we find that the corresponding sequence on non-reduced homology is exact.

$$0 \longrightarrow H_n(X_1) \oplus H_n(X_2) \longrightarrow H_n(X) \longrightarrow 0$$

□

**Definition 132** (good pair). A pair of spaces  $(X, A)$  is said to be a good pair if the following conditions are satisfied.

1.  $A$  is closed inside  $X$ .
2. There exists an open set  $U$  with  $A \subset U$  such that  $A$  is a deformation retract of  $U$ .

$$A \hookrightarrow U \xrightarrow{r} A$$

**Proposition 133.** Let  $(X, A)$  be a good pair. Let  $\pi: X \rightarrow X/A$  be the canonical projection. Then

$$\tilde{H}(X, A) \cong \tilde{H}_n(X/A) \quad \text{for all } n > 0.$$

*Proof.*

□

**Theorem 134** (suspension isomorphism). Let  $(X, A)$  be a good pair. Then

$$H_n(\Sigma X, \Sigma A) \cong \tilde{H}_{n-1}(X, A), \quad \text{for all } n > 0.$$

## 8.7 Mapping degree

We have shown that

$$\tilde{H}_n(\mathbb{S}^m) \cong \begin{cases} \mathbb{Z}, & n = m \\ 0, & n \neq m \end{cases}.$$

Thus, we may pick in each  $H_n(\mathbb{S}^n)$  a generator  $\mu_n$ . Let  $f: \mathbb{S}^n \rightarrow \mathbb{S}^n$  be a continuous map. Then

$$H_n(f)(\mu_n) = d \mu_n, \quad \text{for some } d \in \mathbb{Z}.$$

**Definition 135** (mapping degree). We call  $d \in \mathbb{Z}$  as above the mapping degree of  $f$ , and denote it by  $\deg(f)$ .

**Example 136.** Consider the map

$$\omega: [0, 1] \rightarrow \mathbb{S}^1; \quad t \mapsto e^{2\pi it}.$$

The 1-simplex  $\omega$  generates the fundamental group  $\pi_1(\mathbb{S}^1)$ , so by the Hurewicz homomorphism ([Theorem 112](#)), the class  $[\omega]$  generates  $H_1(\mathbb{S}^1)$ . We can think of  $[\omega]$  as  $1 \in \mathbb{Z}$ .

Now consider the map

$$f_n: \mathbb{S}^1 \rightarrow \mathbb{S}^1; \quad x \mapsto x^n.$$

We have

$$\begin{aligned} H_1(f_n)(\omega) &= [f_n \circ \omega] \\ &= [e^{2\pi i n t}]. \end{aligned}$$

The naturality of the Hurewicz isomorphism ([Theorem 112](#)) tells us that the following diagram commutes.

$$\begin{array}{ccc} \pi_1(\mathbb{S}^1)_{\text{ab}} & \xrightarrow{\pi_1(f_n)_{\text{ab}}} & \pi_1(\mathbb{S}^1)_{\text{ab}} \\ h_{\mathbb{S}^1} \downarrow & & \downarrow h_{\mathbb{S}^1} \\ H_1(\mathbb{S}^1) & \xrightarrow{H_1(f_n)} & H_1(\mathbb{S}^1) \end{array}$$

## 8.8 CW Complexes

CW complexes are a class of particularly nicely-behaved topological spaces.

**Definition 137** (cell). Let  $X$  be a topological space. We say that  $X$  is an  $n$ -cell if  $X$  is homeomorphic to  $\mathbb{R}^n$ . We call the number  $n$  the dimension of  $X$ .

**Definition 138** (cell decomposition). A cell decomposition of a topological space  $X$  is a decomposition

$$X = \bigsqcup_{i \in I} X_i, \quad X_i \cong \mathbb{R}^{n_i}$$

where the disjoint union is of sets rather than topological spaces.

**Definition 139** (CW complex). A Hausdorff topological space is known as a CW complex<sup>2</sup> if it satisfies the following conditions.

<sup>2</sup>[Axiom \(CW2\)](#) is called the *closure-finiteness* condition. This is the ‘C’ in CW complex. [Axiom \(CW3\)](#) says that  $X$  carries the *weak topology* and is responsible for the ‘W’.

(CW1) For every  $n$ -cell  $\sigma \subset X$ , there is a continuous map  $\Phi_\sigma: \mathbb{D}^n \rightarrow X$  such that the restriction of  $\Phi_\sigma$  to  $\mathring{\mathbb{D}}^n$  is a homeomorphism

$$\Phi_\sigma|_{\mathring{\mathbb{D}}^n} \cong \sigma,$$

and  $\Phi_\sigma$  maps  $\mathbb{S}^{n-1} = \partial\mathbb{D}^n$  to the union of cells of dimension of at most  $n - 1$ .

(CW2) For every  $n$ -cell  $\sigma$ , the closure  $\bar{\sigma} \subset X$  has a non-trivial intersection with at most finitely many cells of  $X$ .

(CW3) A subset  $A \subset X$  is closed if and only if  $A \cap \bar{\sigma}$  is closed for all cells  $\sigma \in X$ .

At this point, we define some terminology.

- The map  $\Phi_\sigma$  is called the *characteristic map* of the cell  $\sigma$ .
- Its restriction  $\Phi_\sigma|_{\mathbb{S}^{n-1}}$  is called the *attaching map*.

**Example 140.** Consider the unit interval  $I = [0, 1]$ . This has an obvious CW structure with two 0-cells and one 1-cell. It also has an CW structure with  $n + 1$  0-cells and  $n$  1-cells, which looks like  $n$  intervals glued together at their endpoints.

However, we must be careful. Consider the cell decomposition of the interval with zero-cells

$$\sigma_k^0 = \frac{1}{k} \text{ for } k \in \mathbb{N}^{\geq 1}, \quad \text{and} \quad \sigma_\infty^0 = 0$$

and one-cells

$$\sigma_k^1 = \left( \frac{1}{k}, \frac{1}{k+1} \right), \quad k \in \mathbb{N}^{\geq 1}.$$

At first glance, this looks like a CW decomposition; it certainly satisfies [Axiom \(CW1\)](#) and [Axiom \(CW2\)](#). However, consider the set

$$A = \{a_k \mid k \in \mathbb{N}^{\geq 1}\},$$

where

$$a_k = \frac{1}{2} \left( \frac{1}{k} + \frac{1}{k+1} \right),$$

is the midpoint of the interval  $\sigma_k^1$ . We have  $A \cap \sigma_k^0 = \emptyset$  for all  $k$ , and  $A \cap \sigma_k^1 = \{a_k\}$  for all  $k$ . In each case,  $A \cap \bar{\sigma}_j^i$  is closed in  $\sigma_j^i$ . However, the set  $A$  is not closed in  $I$ , since it does not contain its limit point  $\lim_{n \rightarrow \infty} a_n = 0$ .

**Definition 141** (skeleton, dimension). Let  $X$  be a CW complex, and let

$$X^n = \bigcup_{\substack{\sigma \in X \\ \dim(\sigma) \leq n}} \sigma.$$

We call  $X^n$  the  $n$ -skeleton of  $X$ . If  $X$  is equal to its  $n$ -skeleton but not equal to its  $(n - 1)$ -skeleton, we say that  $X$  is  $n$ -dimensional.

*Note 142.* **Axiom (CW3)** implies that  $X$  carries the direct limit topology, i.e. that

$$X \cong \varinjlim X^n.$$

**Definition 143** (subcomplex, CW pair). Let  $X$  be a CW complex. A subspace  $Y \subset X$  is a subcomplex if it has a cell decomposition given by cells of  $X$  such that for each  $\sigma \subset Y$ , we also have that  $\bar{\sigma} \subset Y$ .

We call such a pair  $(X, Y)$  a CW pair.

**Fact 144.** Let  $X$  and  $Y$  be CW complexes such that  $X$  is locally compact. Then  $X \times Y$  is a CW complex.

**Lemma 145.** Let  $D$  be a subset of a CW complex such that for each cell  $\sigma \subset X$ ,  $D \cap \sigma$  consists of at most one point. Then  $D$  is discrete.

**Corollary 146.** Let  $X$  be a CW complex.

1. Every compact subset  $K \subset X$  is contained in a finite union of cells.
2. The space  $X$  is compact if and only if it is a finite CW complex.
3. The space  $X$  is locally compact<sup>3</sup> if and only if it is locally finite.<sup>4</sup>

*Proof.* It is clear that 1.  $\Rightarrow$  2., since  $X$  is a subset of itself. Similarly, it is clear that 2.  $\Rightarrow$  3., since  $\square$

**Corollary 147.** If  $f: K \rightarrow X$  is a continuous map from a compact space  $K$  to a CW complex  $X$ , then the image of  $K$  under  $f$  is contained in a finite skeleton. That is to say,  $f$  factors through some  $X^n$ .

$$\begin{array}{ccccccc} & & & & & & K \\ & & & & & \nearrow \exists \tilde{f} & \downarrow f \\ X^{n-1} & \hookrightarrow & X^n & \hookrightarrow & X^{n+1} & \hookrightarrow & \dots \hookrightarrow X \end{array}$$

**Proposition 148.** Let  $A$  be a subcomplex of a CW complex  $X$ . Then  $X \times \{0\} \cup A \times [0, 1]$  is a strong deformation retract of  $X \times [0, 1]$ .

**Lemma 149.** Let  $X$  be a CW complex.

- For any subcomplex  $A \subset X$ , there is an open neighborhood  $U$  of  $A$  in  $X$  together with a strong deformation retract to  $A$ . In particular, for each skeleton  $X^n$  there is an open neighborhood  $U$  in  $X$  (as well as in  $X^{n+1}$ ) of  $X^n$  such that  $X^n$  is a strong deformation retract of  $U$ .
- Every CW complex is paracompact, locally path-connected, and locally contractible.

<sup>3</sup>I.e. every point of  $X$  has a compact neighborhood.

<sup>4</sup>I.e. if every point has a neighborhood which is contained in only finitely many cells.

- Every CW complex is semi-locally 1-connected, hence possesses a univesal covering space.

**Lemma 150.** Let  $X$  be a CW complex. We have the following decompositions.

1.

$$X^n \setminus X^{n-1} = \coprod_{\sigma \text{ an } n\text{-cell}} \sigma \cong \coprod_{\sigma \text{ an } n\text{-cell}} \mathring{\mathbb{D}}^n.$$

2.

$$X^n / X^{n-1} \cong \bigvee_{\sigma \text{ an } n\text{-cell}} \mathbb{S}^n$$

*Proof.*

1. Since  $X^n \setminus X^{n-1}$  is simply the union of all  $n$ -cells (which must by definition be disjoint), we have the first equality. The homeomorphism is simply because each  $n$ -cell is homeomorphic to the open  $n$ -ball.
2. For every  $n$ -cell  $\sigma$ , the characteristic map  $\Phi_\sigma$  sends  $\partial\Delta^n$  to the  $(n-1)$ -skeleton.

□

## 8.9 Cellular homology

**Lemma 151.** For  $X$  a CW complex, we always have

$$H_q(X^n, X^{n-1}) \cong \tilde{H}_q(X^n / X^{n-1}) \cong \bigoplus_{\sigma \text{ an } n\text{-cell}} \tilde{H}_q(\mathbb{S}^n).$$

*Proof.* By Lemma 149,  $(X^n, X^{n-1})$  is a good pair. The first isomorphism then follows from Proposition 133, and the second from Lemma 150. □

**Lemma 152.** Consider the inclusion  $i_n: X^n \hookrightarrow X$ .

- The induced map

$$H_n(i_n): H_n(X^n) \rightarrow H_n(X)$$

is surjective.

- On the  $(n+1)$ -skeleton we get an isomorphism

$$H_n(i_{n+1}): H_n(X^{n+1}) \cong H_n(X).$$

*Proof.* Consider the pair of spaces  $(X^{n+1}, X^n)$ . The associated long exact sequence tells us that the sequence

$$H_n(X^n) \longrightarrow H_n(X^{n+1}) \longrightarrow H_n(X^{n+1}, X^n)$$

is exact. But by [Lemma 151](#),

$$H_n(X^{n+1}, X^n) \cong \bigoplus_{\sigma \text{ an } (n+1)\text{-cell}} \tilde{H}_n(\mathbb{S}^{n+1}) \cong 0,$$

so  $H_n(i_n): X^n \hookrightarrow X^{n+1}$  is surjective.

Now let  $m > n$ . The long exact sequence on the pair  $(X^{m+1}, X^m)$  tells us that the following sequence is exact.

$$\begin{array}{c} \xrightarrow{\quad H_{n+1}(X^{m+1}, X^m) \quad} \\ \delta \nearrow \quad \quad \quad \searrow \\ H_n(X^m) \longrightarrow H_n(X^{m+1}) \longrightarrow H_n(X^{m+1}, X^m) \end{array}$$

But again by [Lemma 151](#), both  $H_{n+1}(X^{m+1}, X^m)$  and  $H_n(X^{m+1}, X^m)$  are trivial, so

$$H_n(X^m) \rightarrow H_n(X^{m+1})$$

is an isomorphism.

Now consider  $X$  expressed as a colimit of its skeleta.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & X^n & \longrightarrow & X^{n+1} & \longrightarrow & X^{n+2} \longrightarrow \cdots \\ & & & & \searrow & & \searrow \\ & & & & & & \searrow \\ & & & & & & X \end{array}$$

Taking  $n$ th singular homology, we find the following.

$$\cdots \longrightarrow H_n(X^n) \xrightarrow{\alpha_1} H_n(X^{n+1}) \xrightarrow{\alpha_2} H_n(X^{n+2}) \xrightarrow{\alpha_3} \cdots \longrightarrow H_n(X)$$

Let  $[\alpha] \in H_n(X^n)$ , with

$$\alpha = \sum_i \alpha^i \sigma_i, \quad \sigma_i: \Delta^n \rightarrow X.$$

Since the standard  $n$ -simplex  $\Delta^n$  is compact, [Corollary 147](#) implies that each  $\sigma_i$  factors through some  $X^{n_i}$ . Therefore, each  $\sigma_i$  factors through  $X^N$  with  $N = \max_i n_i$ , and we can write

$$\sigma_i = i_N \circ \tilde{\sigma}_i, \quad \tilde{\sigma}_i: \Delta^n \rightarrow X^N.$$

Now consider

$$\tilde{\alpha} = \sum_i \alpha^i \tilde{\sigma}_i \in S_n(X^N).$$

Thus,

$$[\alpha] = \left[ \sum_i \alpha^i i_n \circ \sigma \right]$$

□

**Corollary 153.** Let  $X$  and  $Y$  be CW complexes.

1. If  $X^n \cong Y^n$ , then  $H_q(X) \cong H_q(Y)$  for all  $q < n$ .
2. If  $X$  has no  $q$ -cells, then  $H_q(X) \cong 0$ .
3. In particular, for an  $n$ -dimensional CW-complex  $X$  (Definition 141),  $H_q(X) = 0$  for  $q > n$ .

*Proof.*

1. This follows immediately from Lemma 152.
- 2.

□

**Definition 154** (cellular chain complex). Let  $X$  be a CW complex. The cellular chain complex of  $X$  is defined level-wise by

$$C_n(X) = H_n(X^n, X^{n-1}),$$

with boundary operator  $d_n$  given by the following composition

$$H_n(X^n, X^{n-1}) \xrightarrow{\delta} H_{n-1}(X^{n-1}) \xrightarrow{\varrho} H_{n-1}(X^{n-1}, X^{n-2})$$

where  $\varrho$  is induced by the projection

$$S_{n-1}(X^{n-1}) \rightarrow S_{n-1}(X^{n-1}, X^{n-2}).$$

This is a bona fide differential, since

$$d^2 = \varrho \circ \delta \circ \varrho \circ \delta,$$

and  $\delta \circ \varrho$  is a composition in the long exact sequence on the pair  $(X^n, X^{n-1})$ .

**Theorem 155** (comparison of cellular and singular homology). Let  $X$  be a CW complex. Then there is an isomorphism

$$\Upsilon_n: H_n(C_\bullet(X), d) \cong H_n(X).$$

**Example 156** (complex projective space). Consider the complex projective space  $\mathbb{C}P^n$ .

## 8 Algebraic topology

We know that  $\mathbb{C}P^0 = \text{pt}$ , and from the homogeneous coordinates

$$[x_0 : \cdots : x_n]$$

on  $\mathbb{C}P^n$ , we have a decomposition

$$\mathbb{C}P^n \cong \mathbb{C}^n \cup \mathbb{C}P^{n-2}.$$

Inductively, we find a decomposition

$$\mathbb{C}P^n \cong \mathbb{C}^n \cup \mathbb{C}^{n-1} \cup \cdots \cup \mathbb{C}^0,$$

giving us a cell decomposition

$$\mathbb{C}P^{2n} \cong \mathbb{R}^{2n} \cup \mathbb{R}^{2n-2} \cup \cdots \cup \mathbb{R}^0.$$

This is a CW complex because

The cellular chain complex is as follows.

$$\begin{array}{ccccccc} 2n & & 2n-1 & & 2n-2 & & \cdots & & 1 & & 0 \\ \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} & \longrightarrow & \cdots & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} \end{array}$$

The differentials are all zero. Thus, we have

$$H_k(\mathbb{C}P^n) = \begin{cases} \mathbb{Z}, & k = 2i, 0 \leq i \leq n \\ 0, & \text{otherwise.} \end{cases}$$

**Example 157** (real projective space). As in the complex case, appealing to homogeneous coordinates gives a cell decomposition

$$\mathbb{R}P^n \cong \mathbb{R}^n \cup \mathbb{R}^{n-1} \cup \cdots \cup \mathbb{R}^0.$$

The cellular chain complex is thus as follows.

$$\begin{array}{ccccccc} n & & n-1 & & n-2 & & \cdots & & 1 & & 0 \\ \mathbb{Z} & \longrightarrow & \mathbb{Z} & \longrightarrow & \mathbb{Z} & \longrightarrow & \cdots & \longrightarrow & \mathbb{Z} & \longrightarrow & \mathbb{Z} \end{array}$$

Unlike the complex case, we don't know how the differentials behave, so we can't calculate the homology directly.

## 8.10 Homology with coefficients

**Definition 158** (homology with coefficients). Let  $G$  be an abelian group, and  $X$  a topological space. The singular chain complex of  $X$  with coefficients in  $G$  is the chain complex

$$S(X; G) = S(X) \otimes_{\mathbb{Z}} G.$$

The  $n$ th singular homology of  $X$  with coefficients in  $G$  is the  $n$ th homology

$$H_n(X; G) = H_n(S(X; G)).$$

We can relate homology with integral coefficients (i.e. standard homology) and homology with coefficients in  $G$ .

**Theorem 159.** For every topological space  $X$  there is a short exact sequence

$$0 \longrightarrow H_n(X) \otimes G \hookrightarrow H_n(X; G) \twoheadrightarrow \text{Tor}(H_{n-1}(X), G) \longrightarrow 0.$$

Furthermore, this sequence splits non-canonically, telling us that

$$H_n(X; G) \cong (H_n(X) \otimes G) \oplus \text{Tor}_1^{\mathbb{Z}}(H_{n-1}(X), G).$$

*Proof.* REF to be updated with UCT. □

## 8.11 The topological Künneth formula

**Theorem 160** (topological Künneth formula). For any topological spaces  $X$  and  $Y$ , we have the following short exact sequence.

$$0 \rightarrow \bigoplus_{p+q=n} H_p(X) \otimes H_q(Y) \hookrightarrow H_n(X \times Y) \twoheadrightarrow \bigoplus_{p+q=n-1} \text{Tor}(H_p(X), H_q(Y)) \rightarrow 0$$

## 8.12 Singular cohomology

**Definition 161** (singular cohomology). Let  $G$  be an abelian group. The singular cochain complex of  $X$  with coefficients in  $G$  is the cochain complex

$$S^{\bullet}(X; G) = \text{Hom}(S_{\bullet}, G)$$

We will denote the evaluation map  $\text{Hom}(A, G) \otimes A \rightarrow G$  using angle brackets  $\langle \cdot, \cdot \rangle$ . In this form, it is usually called the *Kroenecker pairing*.

**Lemma 162.** The Kroenecker pairing

$$\langle \cdot, \cdot \rangle : C^n(X; G) \otimes C_n(X) \rightarrow G$$

descends to a map on homology

$$\langle \cdot, \cdot \rangle : H^n(C^\bullet) \otimes H_n(C_\bullet) \rightarrow G.$$

*Proof.* Let

□
