

1 Homology

1.1 Basic definitions and examples

1.1.1 Ordinary homology

Singular homology is the study of topological spaces by associating to them chain complexes in the following way.

$$\mathbf{Top} \xrightarrow{\text{singular nerve}} \mathbf{Set}_\Delta \xrightarrow{\text{free abelian group}} \mathbf{Ab}_\Delta \xrightarrow{\text{Dold-Kan correspondence}} \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$$

Definition 1 (singular complex, singular homology). Let X be a topological space. The singular chain complex $S_\bullet(X)$ is defined level-wise by

$$S_n(X) = M(\mathcal{F}(\mathbf{Sing}(X)))$$

where \mathcal{F} denotes the free group functor and M is the Moore functor (Definition ??). That is, it has differentials

$$d_n: S_n \rightarrow S_{n-1}; \quad (\alpha: \Delta^n \rightarrow X) \mapsto \sum_{i=0}^n \partial^i \alpha.$$

The singular homology of X is the homology

$$H_n(X) = H_n(S_\bullet(X)).$$

Note that the singular chain complex construction is functorial: any map $f: X \rightarrow Y$ gives a chain map $S(f): S(X) \rightarrow S(Y)$. This immediately implies that the n th homology of a space X is invariant under homeomorphism.

Example 2. Denote by pt the one-point topological space. Then $\mathbf{Sing}(\text{pt})_n = \{*\}$, and the chain complex $S_\bullet(\text{pt})$ is at each level simply \mathbb{Z} .

The differential d_n is given by

$$d_n = \sum_{i=0}^n (-1)^i \partial^i; \quad * \mapsto \sum_{i=0}^n (-1)^i *.$$

1 Homology

If n is odd, then there are as many summands with even sign as there are with odd sign, and they cancel each other out. If n is even, then there is one more term with positive sign than with negative sign, and one ends up with the identity. Thus $S(\text{pt})_\bullet$ is given level-wise as follows.

$$\begin{array}{ccccccccccccccc} \cdots & \xrightarrow{\text{id}} & \mathbb{Z} & \xrightarrow{0} & \mathbb{Z} & \xrightarrow{\text{id}} & \mathbb{Z} & \xrightarrow{0} & \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \cdots \\ & & \parallel & & \parallel & & \parallel & & \parallel & & \parallel & & \\ \cdots & \xrightarrow{d_4} & S_3 & \xrightarrow{d_3} & S_2 & \xrightarrow{d_2} & S_1 & \xrightarrow{d_1} & S_0 & \xrightarrow{d_0} & S_{-1} & \xrightarrow{d_{-1}} & \cdots \end{array}$$

Thus, the n th homology of the point is

$$H_n(\text{pt}) = \begin{cases} \mathbb{Z}, & n = 0 \\ 0, & n \neq 0 \end{cases}.$$

1.1.2 Reduced homology

Recall that in addition to the *ordinary*, or *topologist's simplex category* Δ , there is the so-called *extended*, or *algebraist's simplex category* Δ_+ , which includes the object $[-1] = \emptyset$. If we use this category to index our simplicial sets, our chain complexes have a term $\tilde{S}_{-1} = \mathbb{Z}$. It is traditional to denote the differential $d_0: \tilde{S}_0 \rightarrow \tilde{S}_{-1}$ by ε , and call it the *augmentation map*.

$$\cdots \longrightarrow \tilde{S}_2 \xrightarrow{d_2} \tilde{S}_1 \xrightarrow{d_1} \tilde{S}_0 \xrightarrow{\varepsilon} \mathbb{Z} \longrightarrow 0$$

Definition 3 (reduced singular chain complex). The chain complex \tilde{S} is called the reduced singular chain complex of X .

We see immediately that

$$S_i(X) = \tilde{S}_i(X), \quad i \geq 0,$$

implying

$$H_i(X) = \tilde{H}_i(X), \quad i \geq 1.$$

The difference between ordinary and reduced homology is that, as one might suspect, ordinary homology is better-behaved from a topological point of view, and reduced homology is better behaved algebraically (for example, as a functor reduced homology turns wedge products into direct sums).

There is also another interpretation of reduced homology. Recall that we have used the name *augmentation map* before, when dealing with resolutions. There we reinterpreted the augmentation map ε as a chain map to a complex concentrated in degree zero. We can pull exactly the same trick here, viewing the augmentation map as a map of chain

complexes

$$\begin{array}{ccccccc} \cdots & \longrightarrow & S_2 & \xrightarrow{d_2} & S_1 & \xrightarrow{d_1} & S_0 \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \varepsilon \\ \cdots & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} \longrightarrow 0 \end{array}.$$

Example 4. We can immediately read off that the reduced homology of the point is

$$\tilde{H}_n(\text{pt}) = 0 \quad \text{for all } n.$$

Example 5. Let X be a nonempty path-connected topological space. Then $H_0(X) \cong \mathbb{Z}$. Specifically,

$$\varepsilon: H_0(X) \rightarrow \mathbb{Z}$$

is an isomorphism.

To see this, let $x \in S_0(X)$ be a point. Since $\varepsilon(nx) = n$ for any $n \in \mathbb{Z}$, we know that ε is surjective. If we can show that ε is injective, then we are done.

At face value, ε does not look injective; after all, there are as many elements of $S_0(X)$

consider a general element of $H_0(X)$. Because d_0 is the zero map, $H_n(X)$ is simply the free group generated by the collection of points of X modulo the relation “there is a path from x to y .” However, path-connectedness implies that every two points of X are connected by a path, so every point of X is equivalent to any other. Thus, $H_0(X)$ has only one generator.

Example 6. More generally, for any (not necessarily path connected) space X ,

$$H_0(X) = \mathbb{Z}^{\pi_0(X)}.$$

Suppose that X can be written as a disjoint union

$$X = \bigsqcup_i X_i.$$

Then, since a map

$$\sigma: \Delta^n \rightarrow X$$

cannot hit more than one of the X_i , we have

$$\text{Top}\left(\Delta^n, \bigsqcup_i X_i\right) \cong \bigsqcup_i \text{Top}(\Delta^n, X_i).$$

Thus, since the free abelian group functor \mathcal{F} and the Moore functor M are left adjoint, they preserve colimits and we have

$$S_n\left(\bigsqcup_i X_i\right) \cong \bigoplus_i S_n(X_i).$$

We will come back to reduced homology in [Section 1.7](#), when we have the tools to understand it properly.

1.2 The Hurewicz homomorphism

Let X be a topological space, and let $x \in X$. Let γ be a loop in X which starts and ends at x , i.e.

$$\gamma: \Delta^1 \rightarrow X; \quad \gamma(0) = x = \gamma(1).$$

We can view γ either as a singular 1-simplex in X , or as a representative of a homotopy class in $\pi_1(X, x)$. It turns out that these points of view are compatible.

Lemma 7. The assignment $\gamma \mapsto [\gamma]_{H_1}$ respects homotopy, and thus descends to a map of sets out of $\pi_1(X, x)$.

$$\begin{array}{ccc} \left\{ \begin{array}{l} \text{Loops starting and} \\ \text{ending at } x \end{array} \right\} & \xrightarrow{\text{homology class}} & H_1(X) \\ \text{homotopy class} \downarrow & \nearrow \exists! \tilde{h}_X & \\ \pi_1(X, x) & & \end{array}$$

Proof. Let γ_1 and γ_2 be loops based at x .

First, suppose that $\gamma_1 \stackrel{H}{\sim} \gamma_2$, i.e.

In order to see that

□

The map \tilde{h}_X is very well-behaved.

Lemma 8. For a topological space X and point $x \in X$, the map

$$\tilde{h}_X: \pi_1(X, x) \rightarrow H_1(X)$$

is a group homomorphism.

Proof. We need to show that it sends the identity to the identity and respects composition. □

Because $H_1(X)$ is abelian, \tilde{h}_X descends to a map out of $\pi_1(X, x)_{\text{ab}}$.

Definition 9 (Hurewicz homomorphism). Let X be a path-connected topological space, and let $x \in X$. The Hurewicz homomorphism is the map

$$h_X: \pi_1(X, x)_{\text{ab}} \rightarrow H_1(X).$$

Theorem 10 (Hurewicz). For any path-connected topological space X , the Hurewicz homomorphism is an isomorphism

$$h_X: \pi_1(X, x_0)_{\text{ab}} \cong H_1(X),$$

where $(-)_{\text{ab}}$ denotes the abelianization. Furthermore, the maps h_X form the components of a natural isomorphism.

$$\begin{array}{ccc} & \xrightarrow{(\pi_1)_{\text{ab}}} & \\ \text{Top}_* & \Downarrow h & \text{Ab} \\ & \xleftarrow{H_1} & \end{array}$$

Proof. We construct an inverse explicitly.

For each point $x \in X$, pick a path

$$\gamma_x: \Delta^1 \rightarrow X; \quad \gamma_x(0) = x_0, \quad \gamma_x(1) = x$$

connecting x_0 to x . For $x = x_0$, choose γ_{x_0} to be the constant path.

For each generator $\alpha: \Delta^1 \rightarrow X$ in $H_1(X)$, the concatenation

$$\gamma_{\alpha(0)} * \alpha * \overline{\gamma_{\alpha(1)}}$$

is a path starting and ending at x . We may thus define a map

$$\phi: S_1(X) \rightarrow \pi_1(X, x)_{\text{ab}}$$

on generators by

$$\alpha \mapsto [\gamma_{\alpha(0)} * \alpha * \overline{\gamma_{\alpha(1)}}],$$

and addition via

$$\alpha + \beta \mapsto [\gamma_{\alpha(0)} * \alpha * \overline{\gamma_{\alpha(1)}}][\gamma_{\beta(0)} * \beta * \overline{\gamma_{\beta(1)}}].$$

In order to check that defining this homomorphism on generators descends to a map on homology, we have to check that it sends boundaries $\partial\sigma$ to zero. \square

Example 11. We can now confidently say that

$$H_1(\mathbb{S}^1) = \pi_1(\mathbb{S}^1)_{\text{ab}} = \mathbb{Z},$$

and that

$$H_1(\mathbb{S}^n) = 0, \quad n > 1.$$

Example 12. Denote by Σ_g the two-dimensional surface of genus g . We know that

$$\pi_1(\Sigma_g) = \langle a_1, b_1, \dots, a_{2g}, b_{2g} \mid \prod_{i=1}^g [a_i, b_i] \rangle.$$

The abelianization of this is simply \mathbb{Z}^{2g} , so

$$H_1(\Sigma_g) = \mathbb{Z}^{2g}.$$

Example 13. Since

$$\pi_1(X \times Y) \equiv \pi_1(X) \times \pi_1(Y)$$

and

$$\pi_1(X \vee Y) \equiv \pi_1(X) * \pi_1(Y),$$

we have that

$$H_1(X \times Y) \cong H_1(X) \times H_1(Y) \cong H_1(X \vee Y).$$

1.3 The method of acyclic models

We need to break the flow here for a theorem which will show up several times, called the *method of acyclic models*.

Definition 14 (category with models). A category with models is a pair $(\mathcal{C}, \mathcal{M})$, where \mathcal{C} is a category and $\mathcal{M} \subset \text{Obj}(\mathcal{C})$ is a set of objects of \mathcal{C} .

Definition 15 (free, acyclic functor). Let $(\mathcal{C}, \mathcal{M})$ be a category with models, and let $F: \mathcal{C} \rightarrow \mathbf{Ch}_{\geq 0}(R\text{-}\mathbf{Mod})$.

1. We say that F is acyclic on \mathcal{M} if for each $M \in \mathcal{M}$, $F(M)$ is acyclic in positive degree, i.e. if $H_n(F(M)) = 0$ for $n > 0$.
2. Let J be a set, and $\mathcal{M}_J \subset \mathcal{M}$ a J -indexed set of objects in \mathcal{M} . Note that we allow the possibility that each $M \in \mathcal{M}$ can appear more than once, or not at all.

Let $F_*: \mathcal{C} \rightarrow R\text{-}\mathbf{Mod}$ be a functor. An \mathcal{M}_J -basis for F_* is, for each $j \in J$ an element $m_j \in F_*(M_j)$ (forming an indexed collection $\{m_j \in F_*(M_j)\}_{j \in J}$) such that for any $X \in \mathcal{C}$ the indexed collection

$$\{F_*(f)(m_j)\}_{j \in J, f \in \text{Hom}(M_j, X)}$$

is a basis for $F_*(X)$ as a free R -module; that is, that we can write

$$F_*(X) = \mathbb{Z}\{F_*(f)(m_j)\}_{j \in J, f \in \text{Hom}(M_j, X)}.$$

We say that F is free on \mathcal{M} if for each $q \geq 0$ there exists some set J_q and indexed set \mathcal{M}_{J_q} such that each F_q has an \mathcal{M}_{J_q} -basis.

Example 16. Consider the category \mathbf{Top} with models $\{\Delta^n\}_{n=0,1,\dots}$. The functor $S: \mathbf{Top} \rightarrow \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$ is both free and acyclic. Acyclicity is clear since Δ^n is contractible for all n .

To see freeness, note that the singleton

$$\{\text{id}_{\Delta^n} : \Delta^n \rightarrow \Delta^n\}$$

forms a basis for F_n because the abelian group $S_n(X)$ is free with generating set

$$\{S(\alpha)(\text{id}_{\Delta^n}) = \alpha\}_{\alpha \in \text{Hom}(\Delta^n, X)}.$$

The freeness condition can be interpreted as telling us that in order to know how the functor F behaves on any object, it is enough to know how it behaves on the M_α .

Theorem 17 (acyclic model theorem). Let $(\mathcal{C}, \mathcal{M})$ be a category with models, and let F, G be functors $\mathcal{C} \rightarrow \mathbf{Ch}_{\geq 0}(R\text{-Mod})$ such that F is free on \mathcal{M} and G is acyclic on \mathcal{M} .

1. Any natural transformation $\bar{\tau}_0 : H_0(F) \rightarrow H_0(G)$ is induced by a natural chain map $\tau : F \rightarrow G$.
2. Two natural chain maps $\tau, \tau' : F \rightarrow G$ inducing the same natural transformation $H_0(G) \rightarrow H_0(G')$ are naturally chain homotopic.

Proof.

1. Let $\tau : F \Rightarrow G$ be a natural transformation. First, we collect some results about the natural transformation $\tau_q : F_q \Rightarrow G_q$. Note that, since

$$F_q(X) \cong R\{F_q(f)(m_j)\}_{j \in J_q, f \in \text{Hom}(M_j, X)}$$

we can specify $\tau_q(X)$ (the component of τ_q at X) completely by specifying how it acts on those elements of $F_q(X)$ of the form $F_q(f)(m_j)$, and that we are free in choosing this action.

Consider the following naturality square for some map $f : M_j \rightarrow X$.

$$\begin{array}{ccc}
 F_q(M_j) & \xrightarrow{\tau_q(m_j)} & G_q(M_j) \\
 \downarrow F_q(f) & & \downarrow G_q(f) \\
 & \begin{array}{ccc} m_j \mapsto \tau_q(M_j)(m_j) \\ \downarrow \quad \quad \downarrow \\ F_q(f)(m_j) \mapsto \star \end{array} & \\
 F_q(X) & \xrightarrow{\tau_q(X)} & G_q(X)
 \end{array}$$

Naturality requires that

$$\tau_q(X)(F(f)(m_j)) = G_q(f)(\tau_q(M_j)(m_j)).$$

1 Homology

Thus, in order to define $\tau_q(X)$ for all X , we need only specify how $\tau_q(M_j)$ behaves on $m_j \in F_q(M_j)$. Defining it in this way and extending it by naturality will ensure that the maps we construct form the components of a natural transformation.

For $q = 0$, this is easy, since we have a natural transformation $\bar{\tau}_0$. Since everything in $H_0(F)$ is a cycle, we can define $\tau_0(M_j)(m_j)$ to be any representative of the equivalence class

$$\bar{\tau}_0(M_j)[m_j] \in H_0(G(M_j)).$$

Now suppose we have defined natural transformations τ_{q-1} , for $q > 0$. For $j \in J_q$, we define $\tau_q(M_j(m_j))$ by

$$\partial \tau_q(M_j)(m_j) = \tau_{q-1}(M_j(\partial m_j)).$$

This is well-defined precisely because

$$\partial \tau_{q-1}(M_j)(\partial m_j) = \tau_{q-2}(\partial^2 m_j) = 0$$

since τ_{q-1} is by assumption a chain map and G is by assumption acyclic on \mathcal{M} .

2. One defines a chain homotopy inductively using the same trick.

□

1.4 Homotopy equivalence

We would like that two maps which are homotopic induce the same maps on homology. As alluded to in Section ??, we will see that a homotopy H between maps $f, g: X \rightarrow Y$ induces a chain homotopy h between $S_n(f)$ and $S_n(g)$.

1.4.1 Homotopy invariance: the high brow approach

Proposition 18. Let $f, g: X \rightarrow Y$ be continuous maps between topological spaces, and let $H: X \times [0, 1] \rightarrow Y$ be a homotopy between them. Then H induces a homotopy between $C(f)$ and $C(g)$.

Proof. Suppose we are given a homotopy $f \stackrel{H}{\sim} g$.

$$\begin{array}{ccc}
 X & & \\
 \text{id} \times \{0\} \downarrow & \searrow f & \\
 X \times I & \xrightarrow{H} & X \\
 \text{id} \times \{1\} \uparrow & \nearrow g & \\
 X & &
 \end{array}$$

Consider the functors

$$F = S_\bullet(-), \quad G = S_\bullet(I \times -): \mathbf{Top} \rightarrow \mathbf{Ch}_{\geq 0}(\mathbf{Ab}).$$

Take \mathbf{Top} with models $\mathcal{M} = \{\Delta^q \mid q = 0, 1, \dots\}$, $J_n = \{*\}$, $\mathcal{M}_{J_n} = \{\Delta^n\}$ and $m_* = \text{id}_{\Delta^n}$. For all n , we have that F is free because

$$S_n(X) \cong \mathbb{Z}\{S_n(\alpha)(\text{id}_{\Delta^n}) \mid \alpha \in \text{Hom}(\Delta^n, X)\},$$

and that G is acyclic because $\Delta^n \times I$ is contractible for all n .

Denote by ι_X^0 the map $X \rightarrow X \times I$, which sends $x \mapsto (x, 0)$. Define ι_X^1 analogously.

Consider the natural transformations

$$i^0, i^1: F \Rightarrow G$$

with components

$$i_X^0 = S_\bullet(\iota_X^0), \quad i_X^1 = S_\bullet(\iota_X^1).$$

These clearly agree on H_0 . Thus, by [Theorem 17](#), i^0 and i^1 are chain homotopic via some chain homotopy D .

If D is homotopy between i^0 and i^1 , then $S(H) \circ D$ is a homotopy between $S(H) \circ i^0$ and $S(H) \circ i^1$. But $S(H) \circ i^0 = S(f)$, and $S(H) \circ i^1 = S(g)$. \square

Corollary 19. Any two topological spaces which are homotopy equivalent have the same homology groups.

Example 20. Any contractible space is homotopy equivalent to the one point space pt . Thus, for any contractible space X we have

$$H_n(X) = \begin{cases} \mathbb{Z}, & n = 0 \\ 0, & n \neq 0 \end{cases}$$

1.4.2 Homotopy-invariance: the low-brow approach

Such a homotopy H is a map

$$H: X \times [0, 1] \rightarrow Y.$$

It seems reasonable that we would get the chain homotopy in question by relating the singular homology of X and the singular homology of $X \times [0, 1]$.

Here is the game plan.

- We notice that there are n obvious ways of mapping

$$p_i: \Delta^{n+1} \rightarrow \Delta^n \times [0, 1],$$

1 Homology

and $\Delta^n \times [0, 1]$ is the union of the images, which overlap only along their boundaries.

- Given an n -simplex $\alpha: \Delta^n \rightarrow X$, we can produce an $(n + 1)$ -simplex in $X \times [0, 1]$ by pulling back:

$$P_i: \Delta^{n+1} \rightarrow \Delta^n \times [0, 1] \rightarrow X \times [0, 1].$$

- Given a homotopy

$$H: X \times [0, 1] \rightarrow Y$$

between f and g , we can pull back by the P_i , giving us an $(n + 1)$ -simplex

$$P_i(\alpha): \Delta^{n+1} \rightarrow \Delta^n \times [0, 1] \rightarrow X \times [0, 1] \rightarrow Y.$$

The association

$$\alpha \mapsto P_i \alpha$$

is a homomorphism.

- If we take a sum of the $P_i \alpha$, we get a cellular decomposition of the image of α . However, by taking an alternating sum

$$P = \sum_{i=0}^n P_i$$

we can get (upon passing to boundaries) the interior walls to cancel each other out. Thus, the composition

$$d \circ P$$

gives a cellular decomposition of the boundary of the image of the cylinder. The composition $P \circ d$ gives you a cellular decomposition of the sides of the cylinder with the opposite sign. Thus, the sum $d \circ P + P \circ d$ gives you the (difference of) the top and the bottom of the cylinder.

- This tells us that *homotopic maps between topological spaces induce the same map between homotopy groups*.

1.5 Relative homology

1.5.1 Relative homology

Denote by **Pair** the category whose objects are pairs (X, A) , where X is a topological space and $A \hookrightarrow X$ is a subspace, and whose morphisms $(X, A) \rightarrow (Y, B)$ are maps $f: X \rightarrow Y$ such that $f(A) \subset B$.

Definition 21 (relative homology). Let (X, A) be a pair of spaces. The inclusion $i: A \hookrightarrow$

X induces a map of chain complexes $A \hookrightarrow X$. The relative chain complex of (X, A) is the cokernel of $C_\bullet(i)$.

Since colimits are computed level-wise, the relative chain complex is given by the level-wise quotient

$$S_\bullet(X, A) = S_\bullet(X)/S_\bullet(A).$$

The relative homology of (X, A) is

$$H_n(X, A) = H_n(S_\bullet(X, A)).$$

Lemma 22. For each n , relative homology provides a functor $H_n: \text{Pair} \rightarrow \text{Ab}$.

Proof. Consider the following diagram

$$\begin{array}{ccc} S(X)_\bullet & \xrightarrow{f} & S(Y)_\bullet \\ \downarrow & & \downarrow \\ S(X)_\bullet/S(A)_\bullet & \dashrightarrow & S(Y)_\bullet/S(B)_\bullet \end{array}$$

The dashed arrow is uniquely well-defined because of the assumption that $f(A) \subset B$, meaning that the relative homology construction is well-defined on the level of the relative chain complex. Functoriality of the relative homology now follows from the functoriality of H_n . \square

1.5.2 The long exact sequence on a pair of spaces

Proposition 23. Let (X, A) be a pair of spaces. There is the following long exact sequence.

$$\begin{array}{ccccccc} & & \cdots & \longrightarrow & H_{j+1}(X, A) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ H_j(A) & \longrightarrow & H_j(X) & \longrightarrow & H_j(X, A) & & \\ & \swarrow & & & \searrow & & \\ & & \delta & & & & \\ H_{j-1}(A) & \longrightarrow & \cdots & & & & \end{array}$$

Proof. This is the long exact sequence associated to the following short exact sequence.

$$0 \longrightarrow C_\bullet(A) \hookrightarrow C_\bullet(X) \twoheadrightarrow C_\bullet(X, A) \longrightarrow 0$$

\square

Example 24. Let $X = \mathbb{D}^n$, the n -disk, and $A = \mathbb{S}^{n-1}$ its boundary n -sphere.

1 Homology

Consider the long exact sequence on the pair $(\mathbb{D}^n, \mathbb{S}^{n-1})$.

$$\begin{array}{ccccccc}
 & & & \cdots & \longrightarrow & H_{j+1}(\mathbb{D}^n, \mathbb{S}^{n-1}) & \\
 & \swarrow & & & & \searrow & \\
 & & \delta & & & & \\
 & \swarrow & & & & \searrow & \\
 H_j(\mathbb{S}^{n-1}) & \longrightarrow & H_j(\mathbb{D}^n) & \longrightarrow & H_j(\mathbb{D}^n, \mathbb{S}^{n-1}) & & \\
 & \swarrow & & & & \searrow & \\
 & & \delta & & & & \\
 & \swarrow & & & & \searrow & \\
 H_{j-1}(\mathbb{S}^{n-1}) & \longrightarrow & \cdots & & & &
 \end{array}$$

We know that $H_j(\mathbb{D}^n) = 0$ for $n > 0$ because it is contractible. Thus, exactness forces

$$H_j(\mathbb{D}^n, \mathbb{S}^{n-1}) \cong H_{j-1}(\mathbb{S}^{n-1})$$

for $j > 1$ and $n \geq 1$.

Proposition 25. Suppose $i: A \hookrightarrow X$ is a weak retract, i.e. that there is an $r: X \rightarrow A$ such that $r \circ i = \text{id}_A$.

$$\begin{array}{ccccc}
 A & \xhookrightarrow{i} & X & \xrightarrow{r} & A \\
 & \searrow & & \nearrow & \\
 & & \text{id}_A & &
 \end{array}$$

Then

$$H_n(X) \cong H_n(A) \oplus H_n(X, A).$$

Proof. Applying the functor H_n to the diagram above, we find that

$$H_n(r) \circ H_n(i) = \text{id}_{H_n(A)},$$

implying that $H_n(i)$ is injective. Consider the long exact sequence on the pair (X, A) .

$$\begin{array}{ccccccc}
 & & & \cdots & \longrightarrow & H_{n+1}(X, A) & \\
 & \swarrow & & & & \searrow & \\
 & & \delta & & & & \\
 & \swarrow & & & & \searrow & \\
 H_n(A) & \xhookrightarrow{H_n(i)} & H_n(X) & \longrightarrow & H_n(X, A) & & \\
 & \swarrow & & & & \searrow & \\
 & & \delta & & & & \\
 & \swarrow & & & & \searrow & \\
 H_{n-1}(A) & \xhookrightarrow{H_{n-1}(i)} & \cdots & & & &
 \end{array}$$

The injectivity of $H_n(i)$ implies that the connecting homomorphisms are zero, meaning that the following sequence is short exact for all n .

$$0 \longrightarrow H_n(A) \xhookrightarrow{H_n(i)} H_n(X) \twoheadrightarrow H_n(X, A) \longrightarrow 0$$

As $H_n(r)$ is a left inverse to $H_n(i)$, the sequence above splits from the left, implying by the splitting lemma (Lemma ??) the result. \square

Proposition 26. Let $i: A \rightarrow X$ be a deformation retract,¹ i.e. that there is a homotopy

$$R: X \times [0, 1] \rightarrow X$$

such that the following conditions are satisfied.

1. $R(x, 0) = x$ for all $x \in X$
2. $R(x, 1) \in A$ for all $x \in X$
3. $R(a, 1) = a$ for all $a \in A$

Then $H_n(i): H_n(A) \rightarrow H_n(X)$ is an isomorphism.

Proof. Let

$$r = R(-, 1): X \rightarrow A.$$

Then 3. implies that $r \circ i = \text{id}_A$.

Furthermore, $R(x, -)$ provides a homotopy between $i \circ r$ and id_X . Thus, X and A are homotopy equivalent, and $H_n(i)$ is an isomorphism. \square

Corollary 27. If $i: X \rightarrow A$ is a deformation retract, then $H_n(X, A) = 0$ for all n .

1.5.3 The braided monstrosity on a triple of spaces

Definition 28 (triple of spaces). Let X be a topological space, and let $B \subset A \subset X$ be subspaces. We call (X, A, B) a triple.

A triple of spaces is in particular three pairs of spaces: (X, A) , (X, B) , and (A, B) . All of these have associated long exact sequences. There is also a fourth long exact sequence.

Proposition 29. There is a long exact sequence

$$\begin{array}{ccccccc}
 & & \dots & \longrightarrow & H_{j+1}(A, B) & & \\
 & \swarrow & & & \searrow & \delta & \\
 & & H_j(A, B) & \longrightarrow & H_j(X, B) & \longrightarrow & H_j(X, A) \\
 & \swarrow & & & \searrow & \delta & \\
 & & H_{j-1}(A, B) & \longrightarrow & \dots & &
 \end{array}$$

Proof. This comes from the short exact sequence

$$0 \longrightarrow S_n(A)/S_n(B) \hookrightarrow S_n(X)/S_n(B) \twoheadrightarrow S_n(X)/S_n(A) \longrightarrow 0.$$

¹I believe we only need i to be a homotopy equivalence; a deformation retract is a homotopy equivalence in which one of the two homotopies is an identity.

□

We can put all four of these together in the following handsome commutative diagram.

1.6 Barycentric subdivision

Fact 30. Let X be a topological space, and let $\mathfrak{U} = \{U_i \mid i \in I\}$ be an open cover of X . Denote by

$$S_n^{\mathfrak{U}}(X)$$

the free group generated by those continuous functions

$$\alpha: \Delta^n \rightarrow X$$

whose images are completely contained in some open set in the open cover \mathfrak{U} . That is, such that there exists some i such that $\alpha(\Delta^n) \subset U_i$. The inclusion $S_n^{\mathfrak{U}}(X) \hookrightarrow S_n(X)$ induces a chain structure on $S_{\bullet}^{\mathfrak{U}}(X)$.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & S_2^{\mathfrak{U}}(X) & \longrightarrow & S_1^{\mathfrak{U}}(X) & \longrightarrow & S_0^{\mathfrak{U}}(X) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \longrightarrow & S_2(X) & \longrightarrow & S_1(X) & \longrightarrow & S_0(X) \longrightarrow 0 \end{array}$$

In fact, this inclusion is homotopic to the identity, hence induces an isomorphism

$$H_n^{\mathfrak{U}}(X) := H_n(S^{\mathfrak{U}}(X)_{\bullet}) \cong H_n(X).$$

This fact allows us almost immediately to read of two important theorems.

1.6.1 Excision

Theorem 31 (excision). Let $W \subset A \subset X$ be a triple of topological spaces such that $\bar{W} \subset \mathring{A}$. Then the right-facing inclusions

$$\begin{array}{ccc} A \setminus W & \xhookrightarrow{i} & A \\ \downarrow & & \downarrow \\ X \setminus W & \xhookrightarrow{i} & X \end{array}$$

induce an isomorphism

$$H_n(i): H_n(X \setminus W, A \setminus W) \cong H_n(X, A).$$

That is, when considering relative homology $H_n(X, A)$, we may cut away a subspace from the interior of A without harming anything. This gives us a hint as to the interpretation of relative homology: $H_n(X, A)$ can be interpreted the part of $H_n(X)$ which does not come from A .

1.6.2 The Mayer-Vietoris sequence

Theorem 32 (Mayer-Vietoris). Let X be a topological space, and let $\mathcal{U} = \{X_1, X_2\}$ be an open cover of X , i.e. let $X = X_1 \cup X_2$. Then we have the following long exact sequence.

$$\begin{array}{ccccccc} & & & & \cdots & \longrightarrow & H_{n+1}(X) \\ & & & & \searrow & \delta & \nearrow \\ & & H_n(X_1 \cap X_2) & \longrightarrow & H_n(X_1) \oplus H_n(X_2) & \longrightarrow & H_n(X) \\ & & \nwarrow & \delta & \nearrow & & \\ & & H_{n-1}(X_1 \cap X_2) & \longrightarrow & \cdots & & \end{array}$$

Proof. We can draw our inclusions as the following pushout.

$$\begin{array}{ccc} & X_1 & \\ i_1 \nearrow & & \searrow \kappa_1 \\ X_1 \cap X_2 & & X \\ i_2 \searrow & & \nearrow \kappa_2 \\ & X_2 & \end{array}$$

We have, almost by definition, the following short exact sequence.

$$0 \longrightarrow S_\bullet(X_1 \cap X_2) \xhookrightarrow{(i_1, i_2)} S_\bullet(X_1) \oplus S_\bullet(X_2) \xrightarrow{\kappa_1 - \kappa_2} S_\bullet^{\mathcal{U}}(X) \longrightarrow 0$$

1 Homology

This gives the following long exact sequence on homology.

$$\begin{array}{ccccccc}
 & & & \cdots & \longrightarrow & H_{n+1}^{\text{ll}}(X) & \\
 & \swarrow & & \delta & \searrow & & \\
 H_n(X_1 \cap X_2) & \longrightarrow & H_n(X_1) \oplus H_n(X_2) & \longrightarrow & H_n^{\text{ll}}(X) & & \\
 & \swarrow & & \delta & \searrow & & \\
 H_{n-1}(X_1 \cap X_2) & \longrightarrow & \cdots & & & &
 \end{array}$$

We have seen that $H_n^{\text{ll}}(X) \cong H_n(X)$; the result follows. \square

Example 33 (Homology groups of spheres). We can decompose \mathbb{S}^n as

$$\mathbb{S}^n = (\mathbb{S}^n \setminus N) \cup (\mathbb{S}^n \setminus S),$$

where N and S are the North and South pole respectively. This gives us the following pushout.

$$\begin{array}{ccccc}
 & & \mathbb{S}^n \setminus N & & \\
 & \swarrow & & \searrow & \\
 (\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S) & & & & \mathbb{S}^n \\
 & \searrow & & \swarrow & \\
 & & \mathbb{S}^n \setminus S & &
 \end{array}$$

The Mayer-Vietoris sequence is as follows.

$$\begin{array}{ccccccc}
 & & & \cdots & \longrightarrow & H_{j+1}(\mathbb{S}^n) & \\
 & \swarrow & & \delta & \searrow & & \\
 H_j((\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S)) & \longrightarrow & H_j(\mathbb{S}^n \setminus N) \oplus H_j(\mathbb{S}^n \setminus S) & \longrightarrow & H_j^{\text{ll}}(X) & & \\
 & \swarrow & & \delta & \searrow & & \\
 H_{j-1}((\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S)) & \longrightarrow & \cdots & & & &
 \end{array}$$

We know that

$$\mathbb{S}^n \setminus N \cong \mathbb{S}^n \setminus S \cong \mathbb{D}^n \simeq \text{pt}$$

and that

$$(\mathbb{S}^n \setminus N) \cap (\mathbb{S}^n \setminus S) \cong I \times \mathbb{S}^{n-1} \simeq \mathbb{S}^{n-1},$$

so using the fact that homology respects homotopy, the above exact sequence reduces

(for $j > 1$) to

$$\begin{array}{c}
 \cdots \rightarrow H_{j+1}(\mathbb{S}^n) \\
 \curvearrowleft \quad \delta \quad \curvearrowright \\
 H_j(\mathbb{S}^{n-1}) \longrightarrow 0 \longrightarrow H_j(\mathbb{S}^n) \\
 \curvearrowleft \quad \delta \quad \curvearrowright \\
 H_{j-1}(\mathbb{S}^{n-1}) \rightarrow \cdots
 \end{array}$$

Thus, for $i > 1$, we have

$$H_i(\mathbb{S}^j) \cong H_{i-1}(\mathbb{S}^{j-1}).$$

We have already noted the following facts.

- H_0 counts the number of connected components, so

$$H_0(\mathbb{S}^j) = \begin{cases} \mathbb{Z} \oplus \mathbb{Z}, & j = 0 \\ \mathbb{Z}, & j > 0 \end{cases}$$

- For path connected X , $H_1(X) \cong \pi_1(X)_{\text{ab}}$, so

$$H_1(\mathbb{S}^j) = \begin{cases} \mathbb{Z}, & j = 0 \\ 0, & \text{otherwise} \end{cases}$$

- For $i > 0$, $H_i(\text{pt}) = 0$, so $H_i(\mathbb{S}^0) = 0$.

This gives us the following table.

$j = 3$	\mathbb{Z}	0		
$j = 2$	\mathbb{Z}	0		
$j = 1$	\mathbb{Z}	\mathbb{Z}		
$j = 0$	$\mathbb{Z} \oplus \mathbb{Z}$	0	0	0
$H_i(\mathbb{S}^j)$	$i = 0$	$i = 1$	$i = 2$	$i = 3$

The relation

$$H_i(\mathbb{S}^j) \cong H_{i-1}(\mathbb{S}^{j-1}), \quad i > 1$$

allows us to fill in the above table as follows.

$j = 3$	\mathbb{Z}	0	0	\mathbb{Z}
$j = 2$	\mathbb{Z}	0	\mathbb{Z}	0
$j = 1$	\mathbb{Z}	\mathbb{Z}	0	0
$j = 0$	$\mathbb{Z} \oplus \mathbb{Z}$	0	0	0
$H_i(\mathbb{S}^j)$	$i = 0$	$i = 1$	$i = 2$	$i = 3$

(1.1)

We can immediately replace things we know, finding the following.

$$(a, b) \mapsto (a + b, a + b)$$

$$0 \longrightarrow H_1(\mathbb{S}^1) \hookrightarrow \mathbb{Z} \oplus \mathbb{Z} \xrightarrow{f} \mathbb{Z} \oplus \mathbb{Z} \longrightarrow \mathbb{Z}$$

$$(c, d) \mapsto c - d$$

The kernel of f is the free group generated by (a, a) . Thus, $H_1(\mathbb{S}^1) \cong \mathbb{Z}$.

1.6.3 The relative Mayer-Vietoris sequence

Theorem 35 (relative Mayer-Vietoris sequence). Let X be a topological space, and let $A, B \subset X$ open in $A \cup B$. Denote $\mathfrak{U} = \{A, B\}$.

Then there is a long exact sequence

$$\begin{array}{ccccccc} & & & & \cdots & \longrightarrow & H_{n+1}(X, A \cup B) \\ & & & & \searrow & \delta & \nearrow \\ & & & & H_n(X, A \cap B) & \longrightarrow & H_n(X, A) \oplus H_n(X, B) \longrightarrow H_n(X, A \cup B) \\ & & & & \searrow & \delta & \nearrow \\ & & & & H_{n-1}(X, A \cap B) & \longrightarrow & \cdots \end{array}$$

Proof. Consider the following commuting diagram.

$$\begin{array}{ccccccc} & 0 & & 0 & & 0 & \\ & \downarrow & & \downarrow & & \downarrow & \\ 0 & \longrightarrow & S_n(A \cap B) & \longrightarrow & S_n(A) \oplus S_n(B) & \longrightarrow & S_n^{\mathfrak{U}}(A \cup B) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & S_n(X) & \longrightarrow & S_n(X) \oplus S_n(X) & \longrightarrow & S_n(X) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & S_n(X, A \cap B) & \longrightarrow & S_n(X, A) \oplus S_n(X, B) & \longrightarrow & S_n(X)/S_n^{\mathfrak{U}}(A \cup B) \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ & & 0 & & 0 & & 0 \end{array}$$

All columns are trivially short exact sequences, as are the first two rows. Thus, the nine lemma (Theorem ??) implies that the last row is also exact.

1 Homology

Consider the following map of short exact sequences; the first row is the last column of the above grid.

$$\begin{array}{ccccccc}
 0 & \longrightarrow & S_n^{\mathcal{U}}(A \cup B) & \hookrightarrow & S_n(X) & \twoheadrightarrow & S_n(X)/S_n^{\mathcal{U}}(A \cup B) \longrightarrow 0 \\
 & & \phi \downarrow & & \parallel & & \downarrow \psi \\
 0 & \longrightarrow & S_n(A \cup B) & \longrightarrow & S_n(X) & \twoheadrightarrow & S_n(X, A \cup B) \longrightarrow 0
 \end{array}$$

This gives us, by Lemma ??, a morphism of long exact sequences on homology.

$$\begin{array}{ccccccccc}
 H_n(S_{\bullet}^{\mathcal{U}}(A \cup B)) & \rightarrow & H_n(X) & \rightarrow & H_n(S_{\bullet}(X)/S_{\bullet}^{\mathcal{U}}(A \cup B)) & \rightarrow & H_{n-1}(S_{\bullet}^{\mathcal{U}}(A \cup B)) & \rightarrow & H_{n-1}(X) \\
 \downarrow H_n(\phi) & & \parallel & & \downarrow H_n(\psi) & & \downarrow H_{n-1}(\phi) & & \parallel \\
 H_n(A \cup B) & \longrightarrow & H_n(X) & \longrightarrow & H_n(X, A \cup B) & \longrightarrow & H_{n-1}(A \cup B) & \longrightarrow & H_{n-1}(X)
 \end{array}$$

We have seen (in Fact 30) that $H_i(\phi)$ is an isomorphism for all i . Thus, the five lemma (Theorem ??) tells us that $H_n(\psi)$ is an isomorphism. \square

1.7 Reduced homology

We have seen that reduced homology $\tilde{H}_n(X)$ agrees with $H_n(X)$ in positive degrees, and is missing a copy of \mathbb{Z} in the zeroth degree. There are three equivalent ways of understanding this: one geometric, one algebraic, and one somewhere in between.

1. **Geometric:** Picking any point $x \in X$, one can define the reduced homology of X by

$$\tilde{H}_n(X) = H_n(X, x).$$

2. **In between:** One can define

$$\tilde{H}_n(X) = \ker(H_n(X) \rightarrow H_n(\text{pt})).$$

3. **Algebraic:** One can augment the singular chain complex $C_{\bullet}(X)$ by adding a copy of \mathbb{Z} in degree -1 , so that

$$\tilde{C}_n(X) = \begin{cases} C_n(X), & n \neq -1 \\ \mathbb{Z}, & n = -1. \end{cases}$$

Then one can define

$$\tilde{H}_n(X) = H_n(\tilde{C}_{\bullet}).$$

There is a more modern point of view, which is the one we have taken so far. In con-

structing the singular chain complex of our space X , we used the following composition.

$$\mathbf{Top} \xrightarrow{\mathbf{Sing}} \mathbf{Set}_\Delta \xrightarrow{\mathcal{F}} \mathbf{Ab}_\Delta \xrightarrow{N} \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$$

For many purposes, there is a more natural category than Δ to use: the category $\bar{\Delta}$, which includes the empty simplex $[-1]$. The functor **Sing** now has a component corresponding to (-1) -simplices:

$$\mathbf{Sing}(X)_{-1} = \mathrm{Hom}_{\mathbf{Top}}(\rho([-1]), X) = \mathrm{Hom}_{\mathbf{Top}}(\emptyset, X) = \{*\},$$

since the empty topological space is initial in **Top**. Passing through \mathcal{F} thus gives a copy of \mathbb{Z} as required. Thus, using $\bar{\Delta}$ instead of Δ gives the augmented singular chain complex. These all have the desired effect, and which method one uses is a matter of preference. To see this, note the following.

- $(1 \Leftrightarrow 2)$: Applying the functor $H_n \circ S$ to the diagram

$$\begin{array}{ccccc} \{x\} & \xhookrightarrow{i} & X & \xrightarrow{\epsilon} \twoheadrightarrow & \{x\} \\ & & & \searrow \text{id}_{\{x\}} & \\ & & & & \end{array}$$

one finds that $H_n(i)$ is an injection. Therefore, the connecting homomorphisms for the long exact sequence on the pair (X, x)

$$\cdots \longrightarrow H_{n+1}(X, x) \xrightarrow{\delta} H_n(\{x\}) \xhookrightarrow{i} H_n(X) \longrightarrow \cdots$$

must be zero, so the sequence

$$0 \longrightarrow H_n(\{x\}) \xhookrightarrow{i} H_n(X) \twoheadrightarrow H_n(X, x) \longrightarrow 0$$

is exact. However, we can say more: thanks again to

Proposition 36. Relative homology agrees with ordinary homology in degrees greater than 0, and in degree zero we have the relation

$$H_0(X) \cong \tilde{H}_0(X) \oplus \mathbb{Z},$$

although this isomorphism is not canonical.

Proof. Trivial from algebraic definition. □

Proposition 37. Let $A \subset X$ be a closed subspace, and suppose that A is a deformation retract of an open neighborhood $A \subset U$. Then

$$H_n(X, A) \cong \tilde{H}_n(X/A).$$

Proof. Let $\pi: X \rightarrow X/A$ be the canonical projection, and $b = \pi(A)$. □

1.7.1 Deja vu all over again

Many of our results for regular homology hold also for reduced homology.

Proposition 38. There is a long exact sequence for a pair of spaces

$$\begin{array}{ccccccc}
 & & \cdots & \longrightarrow & \tilde{H}_{j+1}(X, A) & & \\
 & \swarrow & & & \searrow & & \\
 & & \delta & & & & \\
 \tilde{H}_j(A) & \longrightarrow & \tilde{H}_j(X) & \longrightarrow & \tilde{H}_j(X, A) & & \\
 & \swarrow & & & \searrow & & \\
 & & \delta & & & & \\
 \tilde{H}_{j-1}(A) & \longrightarrow & \cdots & & & &
 \end{array}$$

Proposition 39. We have a reduced Mayer-Vietoris sequence.

$$\begin{array}{ccccccc}
 & & \cdots & \longrightarrow & \tilde{H}_{n+1}(X) & & \\
 & \swarrow & & & \searrow & & \\
 & & \delta & & & & \\
 \tilde{H}_n(X_1 \cap X_2) & \longrightarrow & \tilde{H}_n(X_1) \oplus \tilde{H}_n(X_2) & \longrightarrow & \tilde{H}_n(X) & & \\
 & \swarrow & & & \searrow & & \\
 & & \delta & & & & \\
 \tilde{H}_{n-1}(X_1 \cap X_2) & \longrightarrow & \cdots & & & &
 \end{array}$$

Proposition 40. Let $\{(X_i, x_i)\}_{i \in I}$ be a set of pointed topological spaces such that each x_i has an open neighborhood $U_i \subset X_i$ of which it is a deformation retract. Then for any finite $E \subset I$ ² we have

$$\tilde{H}_n \left(\bigvee_{i \in E} X_i \right) \cong \bigoplus_{i \in E} \tilde{H}_n(X_i).$$

Proof. We prove the case of two bouquet summands; the rest follows by induction. We know that

$$X_1 \vee X_2 = (X_1 \vee U_2) \cup (U_1 \vee X_2)$$

is an open cover. Thus, the reduced Mayer-Vietoris sequence of [Proposition 39](#) tells us that the following sequence is exact.

$$0 \longrightarrow \tilde{H}_n(X_1) \oplus \tilde{H}_n(X_2) \longrightarrow \tilde{H}_n(X) \longrightarrow 0$$

In particular, for $n > 0$, we find that the corresponding sequence on non-reduced ho-

²This finiteness condition is not actually necessary, but giving it here avoids a colimit argument.

mology is exact.

$$0 \longrightarrow H_n(X_1) \oplus H_n(X_2) \longrightarrow H_n(X) \longrightarrow 0$$

□

Definition 41 (good pair). A pair of spaces (X, A) is said to be a good pair if the following conditions are satisfied.

1. A is closed inside X .
2. There exists an open set U with $A \subset U$ such that A is a deformation retract of U .

$$A \hookrightarrow U \xrightarrow{r} A$$

Proposition 42. Let (X, A) be a good pair. Let $\pi: X \rightarrow X/A$ be the canonical projection. Then

$$H(X, A) \cong \tilde{H}_n(X/A) \quad \text{for all } n \geq 0.$$

Proof. First, note that since $X \setminus A \cong (X/A) \setminus \{b\}$ and $U \setminus A \cong (U/A) \setminus \{b\}$, we have an isomorphism of pairs

$$(X \setminus A, U \setminus A) \cong ((X/A) \setminus \{b\}, (U/A) \setminus \{b\}). \quad (1.2)$$

Thus, we have the following chain of isomorphisms.

$$\begin{aligned} H_n(X, A) &\cong H_n(X, U) && \left(\begin{array}{l} A \text{ deformation} \\ \text{retract of } U \end{array} \right) \\ &\cong H_n(X \setminus A, U \setminus A) && (\text{excision}) \\ &\cong H_n((X/A) \setminus \{b\}, (U/A) \setminus \{b\}) && (\text{Equation 1.2}) \\ &\cong H_n(X/A, U/A) && (\text{excision}) \\ &\cong H_n(X/A, \{b\}) && \left(\begin{array}{l} \{b\} \text{ deformation} \\ \text{retract of } U/A \end{array} \right) \\ &\cong \tilde{H}_n(X/A) \end{aligned}$$

□

Theorem 43 (suspension isomorphism). Let (X, A) be a good pair. Then

$$H_n(\Sigma X, \Sigma A) \cong \tilde{H}_{n-1}(X, A), \quad \text{for all } n > 0.$$

1.8 Mapping degree

We have shown that

$$\tilde{H}_n(\mathbb{S}^m) \cong \begin{cases} \mathbb{Z}, & n = m \\ 0, & n \neq m \end{cases}.$$

Thus, we may pick in each $H_n(\mathbb{S}^n)$ a generator μ_n . Let $f: \mathbb{S}^n \rightarrow \mathbb{S}^n$ be a continuous map. Then

$$H_n(f)(\mu_n) = d \mu_n, \quad \text{for some } d \in \mathbb{Z}.$$

Definition 44 (mapping degree). We call $d \in \mathbb{Z}$ as above the mapping degree of f , and denote it by $\deg(f)$.

Example 45. Consider the map

$$\omega: [0, 1] \rightarrow \mathbb{S}^1; \quad t \mapsto e^{2\pi i t}.$$

The 1-simplex ω generates the fundamental group $\pi_1(\mathbb{S}^1)$, so by the Hurewicz homomorphism ([Theorem 10](#)), the class $[\omega]$ generates $H_1(\mathbb{S}^1)$. We can think of $[\omega]$ as $1 \in \mathbb{Z}$.

Now consider the map

$$f_n: \mathbb{S}^1 \rightarrow \mathbb{S}^1; \quad x \mapsto x^n.$$

We have

$$\begin{aligned} H_1(f_n)(\omega) &= [f_n \circ \omega] \\ &= [e^{2\pi i n t}]. \end{aligned}$$

The naturality of the Hurewicz isomorphism ([Theorem 10](#)) tells us that the following diagram commutes.

$$\begin{array}{ccc} \pi_1(\mathbb{S}^1)_{\text{ab}} & \xrightarrow{\pi_1(f_n)_{\text{ab}}} & \pi_1(\mathbb{S}^1)_{\text{ab}} \\ h_{\mathbb{S}^1} \downarrow & & \downarrow h_{\mathbb{S}^1} \\ H_1(\mathbb{S}^1) & \xrightarrow{H_1(f_n)} & H_1(\mathbb{S}^1) \end{array}$$

1.9 CW Complexes

CW complexes are a class of particularly nicely-behaved topological spaces.

Definition 46 (cell). Let X be a topological space. We say that X is an n -cell if X is homeomorphic to \mathbb{R}^n . We call the number n the dimension of X .

Definition 47 (cell decomposition). A cell decomposition of a topological space X is a decomposition

$$X = \bigsqcup_{i \in I} X_i, \quad X_i \cong \mathbb{R}^{n_i}$$

where the disjoint union is of sets rather than topological spaces.

Definition 48 (CW complex). A Hausdorff topological space X , together with a cell decomposition, is known as a CW complex³ if it satisfies the following conditions.

(CW1) For every n -cell $\sigma \subset X$, there is a continuous map $\Phi_\sigma: \mathbb{D}^n \rightarrow X$ such that the restriction of Φ_σ to $\mathring{\mathbb{D}}^n$ is a homeomorphism

$$\Phi_\sigma|_{\mathring{\mathbb{D}}^n} \cong \sigma,$$

and Φ_σ maps $\mathbb{S}^{n-1} = \partial\mathbb{D}^n$ to the union of cells of dimension of at most $n - 1$.

(CW2) For every n -cell σ , the closure $\bar{\sigma} \subset X$ has a non-trivial intersection with at most finitely many cells of X .

(CW3) A subset $A \subset X$ is closed if and only if $A \cap \bar{\sigma}$ is closed for all cells $\sigma \in X$.

At this point, we define some terminology.

- The map Φ_σ is called the *characteristic map* of the cell σ .
- Its restriction $\Phi_\sigma|_{\mathbb{S}^{n-1}}$ is called the *attaching map*.

Example 49. Consider the unit interval $I = [0, 1]$. This has an obvious CW structure with two 0-cells and one 1-cell. It also has an CW structure with $n + 1$ 0-cells and n 1-cells, which looks like n intervals glued together at their endpoints.

However, we must be careful. Consider the cell decomposition of the interval with zero-cells

$$\sigma_k^0 = \frac{1}{k} \text{ for } k \in \mathbb{N}^{\geq 1}, \quad \text{and} \quad \sigma_\infty^0 = 0$$

and one-cells

$$\sigma_k^1 = \left(\frac{1}{k}, \frac{1}{k+1} \right), \quad k \in \mathbb{N}^{\geq 1}.$$

At first glance, this looks like a CW decomposition; it certainly satisfies [Axiom \(CW1\)](#) and [Axiom \(CW2\)](#). However, consider the set

$$A = \{a_k \mid k \in \mathbb{N}^{\geq 1}\},$$

where

$$a_k = \frac{1}{2} \left(\frac{1}{k} + \frac{1}{k+1} \right)$$

is the midpoint of the interval σ_k^1 . We have $A \cap \sigma_k^0 = \emptyset$ for all k , and $A \cap \sigma_k^1 = \{a_k\}$ for all k . In each case, $A \cap \bar{\sigma}_j^i$ is closed in σ_j^i . However, the set A is not closed in I , since it does not contain its limit point $\lim_{n \rightarrow \infty} a_n = 0$.

³[Axiom \(CW2\)](#) is called the *closure-finiteness* condition. This is the ‘C’ in CW complex. [Axiom \(CW3\)](#) says that X carries the *weak topology* and is responsible for the ‘W’.

Definition 50 (skeleton, dimension). Let X be a CW complex, and let

$$X^n = \bigcup_{\substack{\sigma \in X \\ \dim(\sigma) \leq n}} \sigma.$$

We call X^n the n -skeleton of X . If X is equal to its n -skeleton but not equal to its $(n-1)$ -skeleton, we say that X is n -dimensional.

Note 51. **Axiom (CW3)** implies that X carries the direct limit topology, i.e. that

$$X \cong \varinjlim X^n.$$

Definition 52 (subcomplex, CW pair). Let X be a CW complex. A subspace $Y \subset X$ is a subcomplex if it has a cell decomposition given by cells of X such that for each $\sigma \subset Y$, we also have that $\bar{\sigma} \subset Y$.

We call such a pair (X, Y) a CW pair.

Fact 53. Let X and Y be CW complexes such that X is locally compact.⁴ Then $X \times Y$ is a CW complex.

Lemma 54. Let D be a subset of a CW complex such that for each cell $\sigma \subset X$, $D \cap \sigma$ consists of at most one point. Then D is discrete.

Corollary 55. Let X be a CW complex.

1. Every compact subset $K \subset X$ is contained in a finite union of cells.
2. The space X is compact if and only if it is a finite CW complex.
3. The space X is locally compact if and only if it is locally finite.⁵

Proof. It is clear that 1. \Rightarrow 2., since X is a subset of itself. Similarly, it is clear that 2. \Rightarrow 3., since \square

Corollary 56. If $f: K \rightarrow X$ is a continuous map from a compact space K to a CW complex X , then the image of K under f is contained in a finite skeleton. That is to say, f factors through some X^n .

$$\begin{array}{ccccccc} & & & & K & & \\ & & & & \downarrow f & & \\ X^{n-1} & \hookrightarrow & X^n & \xleftarrow{\exists \tilde{f}} & X^{n+1} & \hookrightarrow & \dots \hookrightarrow X \end{array}$$

Proposition 57. Let A be a subcomplex of a CW complex X . Then $X \times \{0\} \cup A \times [0, 1]$ is a strong deformation retract of $X \times [0, 1]$.

⁴I.e. if for every point x there is an open neighborhood U containing x and a compact set K containing U .

⁵I.e. if every point has a neighborhood which is contained in only finitely many cells.

Lemma 58. Let X be a CW complex.

- For any subcomplex $A \subset X$, there is an open neighborhood U of A in X together with a strong deformation retract to A . In particular, for each skeleton X^n there is an open neighborhood U in X (as well as in X^{n+1}) of X^n such that X^n is a strong deformation retract of U .
- Every CW complex is paracompact, locally path-connected, and locally contractible.
- Every CW complex is semi-locally 1-connected, hence possesses a univesal covering space.

Lemma 59. Let X be a CW complex. We have the following decompositions.

1.

$$X^n \setminus X^{n-1} = \coprod_{\sigma \text{ an } n\text{-cell}} \sigma \cong \coprod_{\sigma \text{ an } n\text{-cell}} \mathring{\mathbb{D}}^n.$$

2.

$$X^n / X^{n-1} \cong \bigvee_{\sigma \text{ an } n\text{-cell}} \mathbb{S}^n$$

Proof.

1. Since $X^n \setminus X^{n-1}$ is simply the union of all n -cells (which must by definition be disjoint), we have the first equality. The homeomorphism is simply because each n -cell is homeomorphic to the open n -ball.
2. For every n -cell σ , the characteristic map Φ_σ sends $\partial\Delta^n$ to the $(n-1)$ -skeleton.

□

1.10 Cellular homology

Lemma 60. For X a CW complex, we always have

$$H_q(X^n, X^{n-1}) \cong \tilde{H}_q(X^n / X^{n-1}) \cong \bigoplus_{\sigma \text{ an } n\text{-cell}} \tilde{H}_q(\mathbb{S}^n).$$

Proof. By [Lemma 58](#), (X^n, X^{n-1}) is a good pair. The first isomorphism then follows from [Proposition 42](#), and the second from [Lemma 59](#). □

Lemma 61. Consider the inclusion $i_n: X^n \hookrightarrow X$.

- The induced map

$$H_n(i_n): H_n(X^n) \rightarrow H_n(X)$$

is surjective.

1 Homology

- On the $(n + 1)$ -skeleton we get an isomorphism

$$H_n(i_{n+1}): H_n(X^{n+1}) \cong H_n(X).$$

Proof. Consider the pair of spaces (X^{n+1}, X^n) . The associated long exact sequence tells us that the sequence

$$H_n(X^n) \longrightarrow H_n(X^{n+1}) \longrightarrow H_n(X^{n+1}, X^n)$$

is exact. But by [Lemma 60](#),

$$H_n(X^{n+1}, X^n) \cong \bigoplus_{\sigma \text{ an } (n+1)\text{-cell}} \tilde{H}_n(\mathbb{S}^{n+1}) \cong 0,$$

so $H_n(i_n): X^n \hookrightarrow X^{n+1}$ is surjective.

Now let $m > n$. The long exact sequence on the pair (X^{m+1}, X^m) tells us that the following sequence is exact.

$$\begin{array}{c}
 H_{n+1}(X^{m+1}, X^m) \\
 \curvearrowright \delta \quad \quad \quad \curvearrowleft \\
 H_n(X^m) \longrightarrow H_n(X^{m+1}) \longrightarrow H_n(X^{m+1}, X^m)
 \end{array}$$

But again by [Lemma 60](#), both $H_{n+1}(X^{m+1}, X^m)$ and $H_n(X^{m+1}, X^m)$ are trivial, so

$$H_n(X^m) \rightarrow H_n(X^{m+1})$$

is an isomorphism.

Now consider X expressed as a colimit of its skeleta.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & X^n & \longrightarrow & X^{n+1} & \longrightarrow & X^{n+2} \longrightarrow \cdots \\ & & & & & \searrow & \searrow \\ & & & & & & X \end{array}$$

Taking n th singular homology, we find the following.

$$\cdots \longrightarrow H_n(X^n) \xrightarrow{\alpha_1} H_n(X^{n+1}) \xrightarrow{\alpha_2} H_n(X^{n+2}) \xrightarrow{\alpha_3} \cdots \longrightarrow H_n(X)$$

Let $[\alpha] \in H_n(X^n)$, with

$$\alpha = \sum_i \alpha^i \sigma_i, \quad \sigma_i: \Delta^n \rightarrow X.$$

Since the standard n -simplex Δ^n is compact, [Corollary 56](#) implies that each σ_i factors through some X^{n_i} . Therefore, each σ_i factors through X^N with $N = \max_i n_i$, and we can

write

$$\sigma_i = i_N \circ \tilde{\sigma}_i, \quad \tilde{\sigma}_i: \Delta^n \rightarrow X^N.$$

Now consider

$$\tilde{\alpha} = \sum_i \alpha^i \tilde{\sigma}_i \in S_n(X^N).$$

Thus,

$$[\alpha] = \left[\sum_i \alpha^i i_n \circ \sigma \right]$$

□

Corollary 62. Let X and Y be CW complexes.

1. If $X^n \cong Y^n$, then $H_q(X) \cong H_q(Y)$ for all $q < n$.
2. If X has no q -cells, then $H_q(X) \cong 0$.
3. In particular, for an n -dimensional CW-complex X ([Definition 50](#)), $H_q(X) = 0$ for $q > n$.

Proof.

1. This follows immediately from [Lemma 61](#).
- 2.

□

Definition 63 (cellular chain complex). Let X be a CW complex. The cellular chain complex of X is defined level-wise by

$$C_n(X) = H_n(X^n, X^{n-1}),$$

with boundary operator d_n given by the following composition

$$H_n(X^n, X^{n-1}) \xrightarrow{\delta} H_{n-1}(X^{n-1}) \xrightarrow{\varrho} H_{n-1}(X^{n-1}, X^{n-2})$$

where ϱ is induced by the projection

$$S_{n-1}(X^{n-1}) \rightarrow S_{n-1}(X^{n-1}, X^{n-2}).$$

This is a bona fide differential, since

$$d^2 = \varrho \circ \delta \circ \varrho \circ \delta,$$

and $\delta \circ \varrho$ is a composition in the long exact sequence on the pair (X^n, X^{n-1}) .

Theorem 64 (comparison of cellular and singular homology). Let X be a CW complex. Then there is an isomorphism

$$\Upsilon_n: H_n(C_\bullet(X), d) \cong H_n(X).$$

Example 65 (complex projective space). Consider the complex projective space $\mathbb{C}P^n$. We know that $\mathbb{C}P^0 = \text{pt}$, and from the homogeneous coordinates

$$[x_0 : \cdots : x_n]$$

on $\mathbb{C}P^n$, we have a decomposition

$$\mathbb{C}P^n \cong \mathbb{C}^n \sqcup \mathbb{C}P^{n-2}.$$

Inductively, we find a decomposition

$$\mathbb{C}P^n \cong \mathbb{C}^n \sqcup \mathbb{C}^{n-1} \sqcup \cdots \sqcup \mathbb{C}^0,$$

giving us a cell decomposition

$$\mathbb{C}P^{2n} \cong \mathbb{R}^{2n} \sqcup \mathbb{R}^{2n-2} \sqcup \cdots \sqcup \mathbb{R}^0.$$

This is a CW complex because

The cellular chain complex is as follows.

$$\begin{array}{ccccccc} 2n & & 2n-1 & & 2n-2 & & \cdots & & 1 & & 0 \\ \mathbb{Z} & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} & \longrightarrow & \cdots & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} \end{array}$$

The differentials are all zero. Thus, we have

$$H_k(\mathbb{C}P^n) = \begin{cases} \mathbb{Z}, & k = 2i, 0 \leq i \leq n \\ 0, & \text{otherwise.} \end{cases}$$

Example 66 (real projective space). As in the complex case, appealing to homogeneous coordinates gives a cell decomposition

$$\mathbb{R}P^n \cong \mathbb{R}^n \sqcup \mathbb{R}^{n-1} \sqcup \cdots \sqcup \mathbb{R}^0.$$

The cellular chain complex is thus as follows.

$$\begin{array}{ccccccc} n & n-1 & n-2 & \cdots & 1 & 0 \\ \mathbb{Z} & \longrightarrow & \mathbb{Z} & \longrightarrow & \mathbb{Z} & \longrightarrow & \cdots \longrightarrow \mathbb{Z} \longrightarrow \mathbb{Z} \end{array}$$

Unlike the complex case, we don't know how the differentials behave, so we can't calculate the homology directly.

1.11 Homology with coefficients

Definition 67 (homology with coefficients). Let G be an abelian group, and X a topological space. The singular chain complex of X with coefficients in G is the chain complex

$$S(X; G) = S(X) \otimes_{\mathbb{Z}} G.$$

The n th singular homology of X with coefficients in G is the n th homology

$$H_n(X; G) = H_n(S(X; G)).$$

We can relate homology with integral coefficients (i.e. standard homology) and homology with coefficients in G .

Theorem 68 (topological universal coefficient theorem for homology). For every topological space X there is a short exact sequence

$$0 \longrightarrow H_n(X) \otimes G \hookrightarrow H_n(X; G) \twoheadrightarrow \text{Tor}(H_{n-1}(X), G) \longrightarrow 0.$$

Furthermore, this sequence splits non-canonically, telling us that

$$H_n(X; G) \cong (H_n(X) \otimes G) \oplus \text{Tor}_1^{\mathbb{Z}}(H_{n-1}(X), G).$$

Proof. [Theorem 68](#). □

1.12 The topological Künneth formula

Let X and Y be topological spaces. Plugging $C = S(X)$ and $D = S(Y)$ into Theorem ?? tells us that the following sequence is split exact.

$$0 \rightarrow \bigoplus_{p+q=n} H_p(X) \otimes H_q(Y) \hookrightarrow H_n(S(X)_{\bullet} \otimes S(Y)_{\bullet}) \twoheadrightarrow \bigoplus_{p+q=n-1} \text{Tor}_1(H_p(X), H_q(Y)) \rightarrow 0.$$

It turns out that we can relate $H_n(S(X)_\bullet \otimes S(Y)_\bullet)$ and $H_n(X \times Y)$. In fact, they turn out to be isomorphic; this is known as the *Eilenberg-Zilber theorem*.

1.12.1 The Eilenberg-Zilber theorem: the high-brow approach

This turns out to be a direct consequence of the acyclic model theorem ([Theorem 17](#)).

Lemma 69. The functors

$$F = S(-) \otimes S(-): \mathbf{Top} \times \mathbf{Top} \rightarrow \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$$

and

$$G = S(- \times -): \mathbf{Top} \times \mathbf{Top} \rightarrow \mathbf{Ch}_{\geq 0}(\mathbf{Ab})$$

are both free and acyclic ([Definition 15](#)) on

$$\mathcal{M} = \{(\Delta^p, \Delta^q)\}_{p,q=0,1,\dots}.$$

Proof. Clear, basically. □

Proposition 70. There is a chain homotopy equivalence between F and G as defined in [Lemma 69](#).

Proof. Consider the following diagram.

$$\begin{array}{ccc} & f_0: x \otimes y \mapsto (x, y) & \\ & \curvearrowright & \\ S_0(X) \otimes S_0(Y) & & S_0(X \times Y) \\ & \curvearrowleft & \\ & g_0: (x, y) \mapsto x \otimes y & \end{array}$$

We can find lifts... □

1.12.2 The Eilenberg-Zilber theorem: the low-brow approach

We first define a so-called *homology cross product*

$$\times: S_p(X) \otimes S_q(Y) \rightarrow S_{p+q}(X \times Y),$$

and then show that it descends to homology.

Our goal is to find a way of making a p -simplex in X and a q -simplex in Y into a $(p+q)$ -simplex in $X \times Y$, called the *homology cross product*. At least in the case that one of p or q is equal to zero, it is clear what to do, since the Cartesian product of a p -simplex with a zero-simplex is in an obvious way a p -simplex. In more general cases, however,

we have to be clever. The strategy is to write down a list of properties that we would like our homology cross product to have, and then show that there exists a unique map satisfying them.

Lemma 71. We can define a homomorphism

$$\times: S_p(X) \otimes S_q(Y) \rightarrow S_{p+q}(X \times Y), \quad p, q \geq 0,$$

with the following properties.

1. For all points $x_0 \in X$ viewed as zero-chains in $S_0(X)$ and all $\beta: \Delta^q \rightarrow Y$, we have

$$(x_0 \times \beta)(t_0, \dots, t_q) = (x_0, \beta(t_0, \dots, t_q));$$

conversely, for $\alpha \in S_p(X)$ and $y_0 \in Y$, we have

$$(\alpha \times y_0)(t_0, \dots, t_p) = (\alpha(t_0, \dots, t_p), y_0).$$

2. The map \times is natural in the sense that the square

$$\begin{array}{ccc} S_p(X) \otimes S_q(Y) & \xrightarrow{\times} & S_{p+q}(X \times Y) \\ \downarrow & & \downarrow \\ S_p(X') \otimes S_q(Y') & \xrightarrow{\times} & S_{p+q}(X' \times Y') \end{array}$$

commutes.

3. The map \times satisfies the Leibniz rule in the sense that

$$\partial(\alpha \times \beta) = \partial(\alpha) \times \beta + (-1)^p \alpha \times \partial(\beta).$$

Proof. As a warm up, let us work out some hypothetical consequences of our formulae, in the special case that $X = \Delta^p$ and $Y = \Delta^q$. In this case, we have

$$\text{id}_{\Delta^p} \in S_p(\Delta^p), \quad \text{id}_{\Delta^q} \in S_q(\Delta^q),$$

so we can take the homology cross product $\text{id}_{\Delta^p} \times \text{id}_{\Delta^q} \in S_{p+q}(\Delta^p \times \Delta^q)$. By the Leibniz rule, we have

$$\partial(\text{id}_{\Delta^p} \times \text{id}_{\Delta^q}) = \partial(\text{id}_{\Delta^p}) \times \text{id}_{\Delta^q} + (-1)^p \text{id}_{\Delta^p} \times \partial(\text{id}_{\Delta^q}).$$

This is now a perfectly well-defined element of $S_{p+q-1}(\Delta^p \times \Delta^q)$, which we will give the nickname R .⁶

A trivial computation shows that $\partial R = 0$, so there exists a $c \in S_{p+q}(\Delta^p \times \Delta^q)$ with $\partial c = R$.

⁶I think there's an induction argument hidden here.

1 Homology

We choose some such c and define $\text{id}_{\Delta^p} \times \text{id}_{\Delta^q} = c$.

We now use the trick of expressing some $\alpha: \Delta^p \rightarrow X$ as $S_p(\alpha)(\text{id}_{\Delta^p})$. Then

$$\alpha \times \beta = S_p(\alpha)(\text{id}_{\Delta^p}) \times S_q(\beta)(\text{id}_{\Delta^q}).$$

But then the naturality forces our hand; chasing $\text{id}_{\Delta^p} \otimes \text{id}_{\Delta^q}$ around the naturality square

$$\begin{array}{ccc} S_p(\Delta^p) \otimes S_q(\Delta^q) & \xrightarrow{\times} & S_{p+q}(\Delta^p \times \Delta^q) \\ S_p(\alpha) \otimes S_q(\beta) \downarrow & & \downarrow S_{p+q}(\alpha, \beta) \\ S_p(X) \otimes S_q(Y) & \xrightarrow{\times} & S_{p+q}(X \times Y) \end{array}$$

tells us that

$$\begin{aligned} S_{p+q}(\alpha, \beta)(\text{id}_{\Delta^p} \times \text{id}_{\Delta^q}) &= S_p(\alpha)(\text{id}_{\Delta^p}) \times S_q(\beta)(\text{id}_{\Delta^q}) \\ S_{p+q}(\alpha, \beta)(c) &= \alpha \times \beta. \end{aligned}$$

Thus, we can define

$$\alpha \times \beta = S_{p+q}(\alpha, \beta)(c).$$

This satisfies all the desired properties by construction. \square

Proposition 72. Any natural transformations f, g with components

$$f_{X,Y}, g_{X,Y}: (S(X) \otimes S(Y))_{\bullet} \rightarrow S_{\bullet}(X \times Y)$$

which agree in degree zero and send $x_0 \otimes y_0 \mapsto (x_0, y_0)$ are chain homotopic.

Proof. First, suppose that $X = \Delta^p$ and $Y = \Delta^q$. Then $(S(\Delta^p) \otimes S(\Delta^q))_{\bullet}$ is free, hence certainly projective, and $S(\Delta^p \times \Delta^q)$ is acyclic, so the result follows from Lemma ??: that is, we get a chain homotopy H with components

$$H_n: (S_{\bullet}(\Delta^p) \otimes S_{\bullet}(\Delta^q))_n \rightarrow S_{n+1}(\Delta^p \times \Delta^q)$$

such that

$$\partial H_n + H_{n-1} \partial = f_n - g_n.$$

\square

1.12.3 The topological Künneth formula

Theorem 73 (topological Künneth formula). For any topological spaces X and Y , we have the following short exact sequence, natural in X and Y .

$$0 \rightarrow \bigoplus_{p+q=n} H_p(X) \otimes H_q(Y) \hookrightarrow H_n(X \times Y) \twoheadrightarrow \bigoplus_{p+q=n-1} \text{Tor}(H_p(X), H_q(Y)) \rightarrow 0$$

This sequence splits, but not canonically, and the splitting is not natural.

Example 74. Consider the torus $T^2 \cong \mathbb{S}^1 \times \mathbb{S}^1$. We have that the following sequence is exact.

$$0 \rightarrow \bigoplus_{p+q=n} H_p(\mathbb{S}^1) \otimes H_q(\mathbb{S}^1) \rightarrow H_n(\mathbb{S}^1 \times \mathbb{S}^1) \rightarrow \bigoplus_{p+q=n-1} \text{Tor}(H_p(\mathbb{S}^1), H_q(\mathbb{S}^1)) \rightarrow 0$$

Because $H_i(\mathbb{S})$ is either 0 or \mathbb{Z} , hence certainly projective, we get that

$$H_n(\mathbb{S}^1 \times \mathbb{S}^1) \cong \bigoplus_{p+q=n} H_p(\mathbb{S}) \otimes H_q(\mathbb{S}) \cong \begin{cases} \mathbb{Z} & n = 0 \\ \mathbb{Z}^2 & n = 1 \\ \mathbb{Z} & n = 2 \\ 0 & \text{otherwise.} \end{cases}$$

By induction, $H_n(\mathbb{S}^k) = \mathbb{Z}^{\binom{n}{k}}$.

Example 75. For a space of the form $X \times \mathbb{S}^n$, we get

$$H_n(X \times \mathbb{S}^n) \cong H_n(X) \oplus H_{n-n}(X).$$

1.13 The Eilenberg-Steenrod axioms

Denote by T the functor

$$T: \text{Pair} \rightarrow \text{Pair}; \quad (X, A) \mapsto (A, \emptyset); \quad (f: (X, A) \rightarrow (Y, B)) \mapsto f|_A.$$

Definition 76 (homology theory). Let A be an abelian group. A homology theory with coefficients in A is a sequence of functors

$$H_n: \text{Pair} \rightarrow \text{Ab}, \quad n \geq 0$$

together with natural transformations

$$\delta: H_n \Rightarrow H_{n-1} \circ T$$

1 Homology

satisfying the following conditions.

1. **Homotopy:** Homotopic maps induce the same maps on homology; that is,

$$f \sim g \implies H_n(f) = H_n(g) \quad \text{for all } f, g, n.$$

2. **Excision:** If (X, A) is a pair with $U \subset X$ such that $\bar{U} \subset \mathring{A}$, then the inclusion $i: (X \setminus U, A \setminus U) \hookrightarrow (X, A)$ induces an isomorphism

$$H_n(i): H_n(X \setminus U, A \setminus U) \cong H_n(X, A)$$

for all n .

3. **Dimension:** We have

$$H_n(\text{pt}) = \begin{cases} \mathbb{Z}, & n = 0 \\ 0, & \text{otherwise.} \end{cases}$$

4. **Additivity:** If $X = \coprod_{\alpha} X_{\alpha}$ is a disjoint union of topological spaces, then

$$H_n(X) = \bigoplus_{\alpha} H_n(X_{\alpha}).$$

5. **Exactness:** Each pair (X, A) induces a long exact sequence on homology.

We have seen that singular homology satisfies all of these axioms, and hence is a homology theory.

2 Cohomology

2.1 Axiomatic description of a cohomology theory

There are dual axioms to the Eilenberg-Steenrod axioms (introduced in [Definition 76](#)) which govern cohomology theories.

Definition 77 (cohomology theory). Let A be an abelian group. A cohomology theory with coefficients in A is a series of functors

$$H^n: \mathbf{Pair}^{\text{op}} \rightarrow \mathbf{Ab}; \quad n \geq 0$$

together with natural transformations

$$\partial: H^n \circ T^{\text{op}} \Rightarrow H^{n+1}$$

satisfying the following conditions.

1. **Homotopy:** If f and g are homotopic maps of pairs, then $H^n(f) = H^n(g)$ for all n .
2. **Excision:** If (X, A) is a pair with $U \subset X$ such that $\bar{U} \subset \mathring{A}$, then the inclusion $i: (X \setminus U, A \setminus U) \hookrightarrow (X, A)$ induces an isomorphism

$$H^n(i): H^n(X, A) \cong H^n(X \setminus U, A \setminus U)$$

for all n .

3. **Dimension:** We have

$$H^n(\text{pt}) = \begin{cases} A, & n = 0 \\ 0, & \text{otherwise.} \end{cases}$$

4. **Additivity:** If $X = \coprod_{\alpha} X_{\alpha}$ is a disjoint union of topological spaces, then

$$H^n(X) = \prod_{\alpha} H^n(X_{\alpha}).$$

5. **Exactness:** Each pair (X, A) induces a long exact sequence on cohomology.

2.2 Singular cohomology

Definition 78 (singular cohomology). Let G be an abelian group. The singular cochain complex of X with coefficients in G is the cochain complex

$$S^\bullet(X; G) = \text{Hom}(S_\bullet, G)$$

We will denote the evaluation map $\text{Hom}(A, G) \otimes A \rightarrow G$ using angle brackets $\langle \cdot, \cdot \rangle$. In this form, it is usually called the *Kroenecker pairing*.

Lemma 79. Let C_\bullet be a chain complex. The evaluation map (also known as the *Kroenecker pairing*)

$$\langle \cdot, \cdot \rangle : C^n(X; G) \otimes C_n(X) \rightarrow G$$

descends to a map on homology

$$\langle \cdot, \cdot \rangle : H^n(C^\bullet) \otimes H_n(C_\bullet) \rightarrow G.$$

Proof. Let $\alpha : C_n \rightarrow G \in C^n$ be a cocycle and $a \in C_n$ a cycle, and let $db \in C_n$ be a boundary. Then

$$\begin{aligned} \langle \alpha, a + db \rangle &= \langle \alpha, a \rangle + \langle \alpha, db \rangle \\ &= \langle \alpha, a \rangle + \langle \delta\alpha, b \rangle \\ &= \langle \alpha, a \rangle. \end{aligned}$$

Furthermore, if $\delta\beta \in C^n$ is a cocycle, then

$$\begin{aligned} \langle \alpha + \delta\beta, a \rangle &= \langle \alpha, a \rangle + \langle \delta\beta, a \rangle \\ &= \langle \alpha, a \rangle + \langle \beta, da \rangle \\ &= \langle \alpha, a \rangle \end{aligned}$$

□

Via \otimes -hom adjunction, we get a map

$$\kappa : H^n(C^\bullet) \rightarrow \text{Hom}(H_n(C_\bullet), G).$$

Theorem 80 (universal coefficient theorem for singular cohomology). Let X be a topological space, and G an abelian group. There is a split exact sequence

$$0 \longrightarrow \text{Ext}(H_{n-1}(X), G) \hookrightarrow H^n(X; G) \twoheadrightarrow \text{Hom}(H_n(X), G) \longrightarrow 0$$

Example 81. We have seen (in [Example 65](#)) that the homology of $\mathbb{C}P^n$ is

$$H_k(\mathbb{C}P^n) = \begin{cases} \mathbb{Z}, & 0 \leq k \leq 2n, k \text{ even}, \\ 0, & \text{otherwise.} \end{cases}$$

Thus, for $0 \leq k \leq n$, k even, we find

$$\begin{aligned} H^k(\mathbb{C}P^n; \mathbb{Z}) &\cong \text{Ext}^1(0, \mathbb{Z}) \oplus \text{Hom}(\mathbb{Z}, \mathbb{Z}) \\ &\cong \mathbb{Z}. \end{aligned}$$

For k odd with $0 \leq k \leq n$, we have

$$\begin{aligned} H^k(\mathbb{C}P^n; \mathbb{Z}) &\cong \text{Ext}^1(\mathbb{Z}, \mathbb{Z}) \oplus \text{Hom}(0, \mathbb{Z}) \\ &\cong 0. \end{aligned}$$

For $k > n$, we get $H^k(\mathbb{C}P^n; \mathbb{Z}) = 0$.

2.3 The cap product

The Kroenecker pairing gives us a natural evaluation map

$$S^n(X) \otimes S_n(X) \rightarrow \mathbb{Z},$$

allowing an n -cochain to eat an n -chain. A cochain of order q cannot directly act on a chain of degree $n > q$, but we can split such a chain up into a singular q -simplex, on which our cochain can act, and a singular $n - q$ -simplex, which is along for the ride.

Definition 82 (front, rear face). Let $a: \Delta^n \rightarrow X$ be a singular n -simplex, and let $0 \leq q \leq n$.

- The $(n - q)$ -dimensional front face of a is given by

$$F^{n-q}(a) = \Delta^{n-q} \xrightarrow{i} \Delta^{tn} \xrightarrow{a} X ,$$

where i is induced by the inclusion

$$\{0, \dots, n - q\} \hookrightarrow \{1, \dots, n\}; \quad k \mapsto k.$$

- The q -dimensional rear face of a is given by

$$R^q(a) = \Delta^q \xrightarrow{r} \Delta^n \xrightarrow{a} X ,$$

2 Cohomology

where r is the map

$$\{0, \dots, q\} \rightarrow \{0, \dots, n\}; \quad k \mapsto n - q + k.$$

The cap product will be a map

$$\frown: S^q(X) \otimes S_n(X) \rightarrow S_{n-q}(X); \quad \alpha \otimes a \mapsto F^{n-q}(a) \langle \alpha, R^q(a) \rangle.$$

However, we will want to generalize slightly, to arbitrary coefficient systems and relative homology.

Definition 83 (cap product). The cap product is the map

$$\frown: S^q(X, A; R) \otimes S_n(X, A; R) \rightarrow S_{n-q}(X; R); \quad \alpha \otimes a \otimes r \mapsto F^{n-q}(a) \otimes \langle \alpha, R^q(a) \rangle r.$$

Of course, we need to check that this is well-defined, i.e. that for $b \in S_n(A) \subset S_n(X)$, we have $\alpha \frown b = 0$. We compute

$$\alpha \frown b = F^{n-1}(b) \otimes \langle \alpha, R^q(b) \rangle.$$

Since $b \in S_n(A)$, we certainly have that $R^q(b) \in S_n(A)$. But then $\langle \alpha, R^q(b) \rangle = 0$ by definition of relative cohomology.

Lemma 84. The cap product obeys the Leibniz rule, in the sense that

$$\partial(\alpha \frown (a \otimes r)) = (\delta\alpha) \frown (a \otimes r) + (-1)^q \alpha \frown (\partial a \otimes r).$$

Proposition 85. The cup product descends to a map on homology; that is, we get a map

$$\frown: H^q(X, A; R) \otimes H_n(X, A; R) \rightarrow H_{n-q}(X; R); \quad [\alpha \otimes a \otimes r] \mapsto [F^{n-q}(a) \otimes \langle \alpha, R^q(a) \rangle r].$$
